# What Is Big ... err... “Copious” Data?

**DevOps Borat** @DEVOPS\_BORAT

Big Data is any thing which is crash Excel.

[Expand](#)

8 Jan

**DevOps Borat** @DEVOPS\_BORAT

Small Data is when is fit in RAM. Big Data is when is crash because is not fit in RAM.

[Expand](#)

6 Feb

# Copious Data

Data so big that traditional solutions are too slow, too small, or too expensive to use.

Hat tip: Bob Korbus

“Big Data” a buzz word, but generally associated with the problem of data sets too big to manage with traditional SQL databases. A parallel development has been the NoSQL movement that is good at handling semistructured data, scaling, etc.

# 3 Trends

Copyright © 2011-2013, Dean Wampler. All Rights Reserved

Sunday, July 7, 13

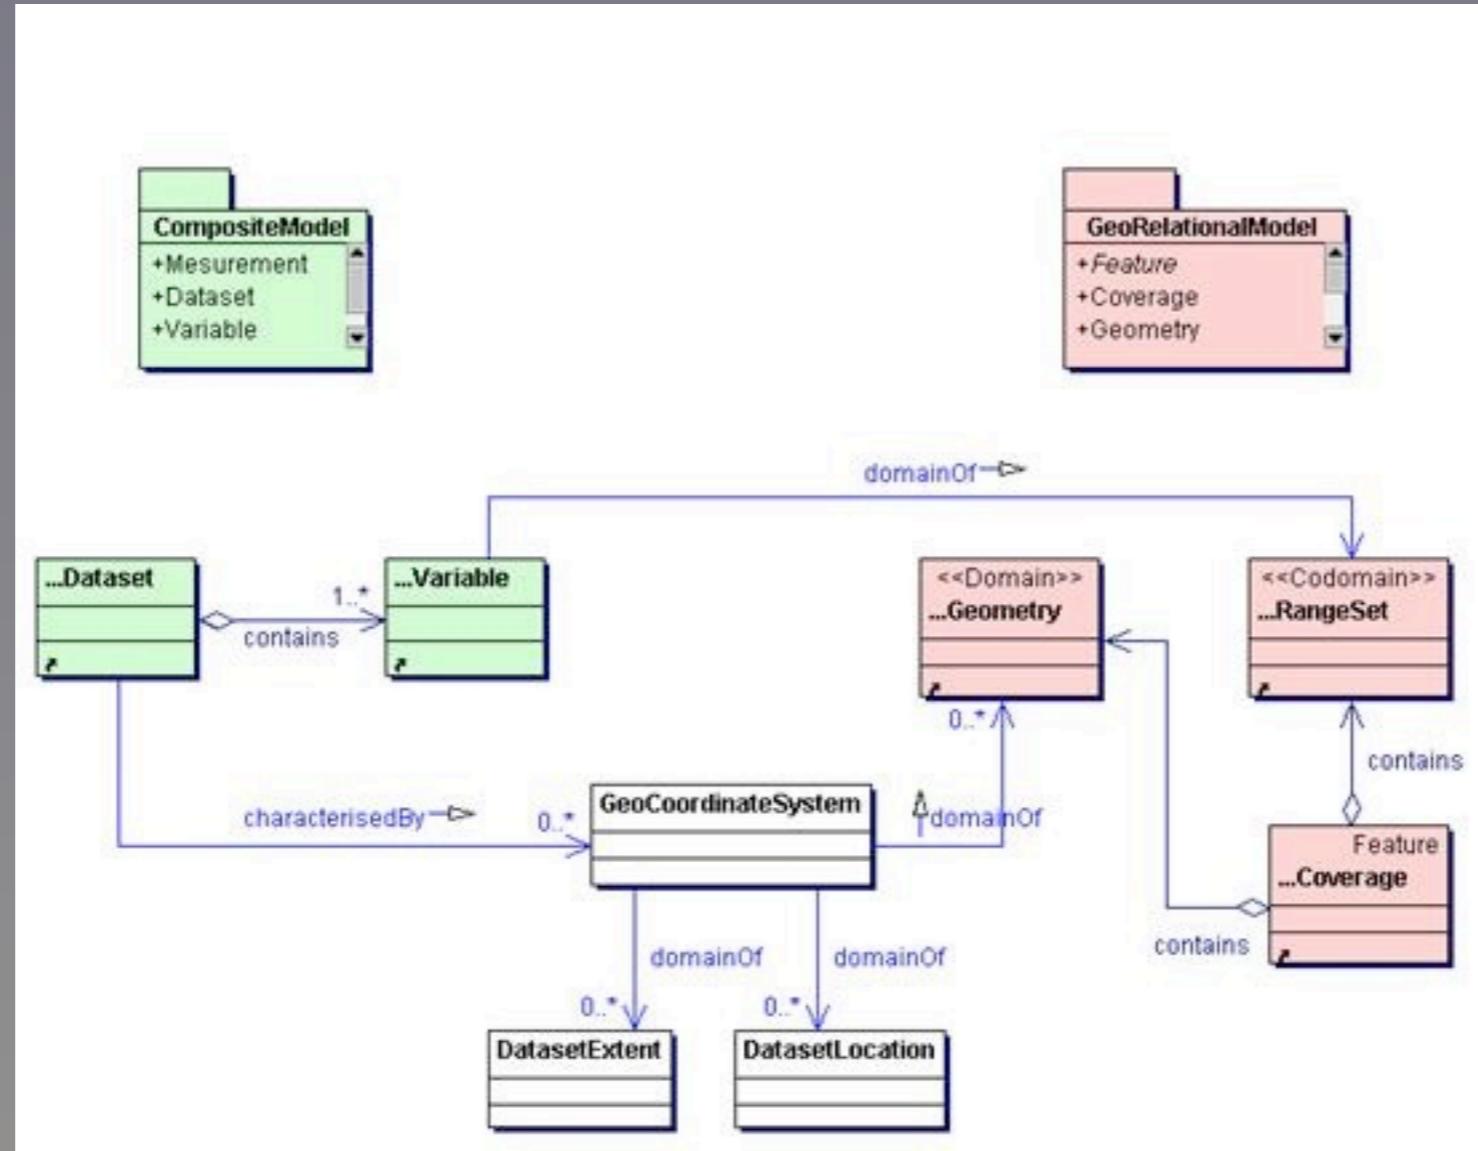

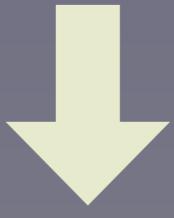

Three trends influence my thinking...

Photo: Prizker Pavilion, Millenium Park

# Data Size ↑

# Formal Schemas

There is less emphasis on “formal” schemas and domain models, i.e., both relational models of data and OO models, because data schemas and sources change rapidly, and we need to integrate so many disparate sources of data. So, using relatively-agnostic software, e.g., collections of things where the software is more agnostic about the structure of the data and the domain, tends to be faster to develop, test, and deploy. Put another way, we find it more useful to build somewhat agnostic applications and drive their behavior through data...

# Data-Driven Programs ↑

Sunday, July 7, 13

This is the 2nd generation “Stanley”, the most successful self-driving car ever built (by a Google-Stanford) team. Machine learning is growing in importance. Here, generic algorithms and data structures are trained to represent the “world” using data, rather than encoding a model of the world in the software itself. It’s another example of generic algorithms that produce the desired behavior by being application agnostic and data driven, rather than hard-coding a model of the world. (In practice, however, a balance is struck between completely agnostic apps and some engineering towards for the specific problem, as you might expect...)

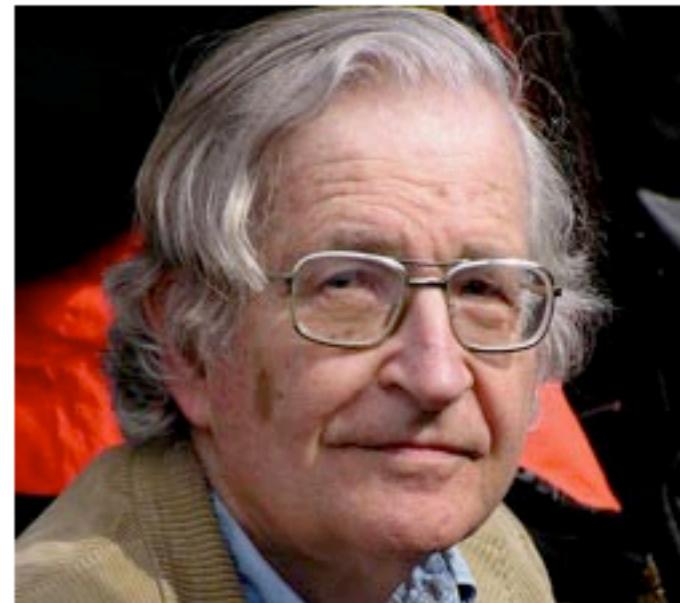

# Probabilistic Models vs. Formal Grammars

[tor.com/blogs/...](http://www.tor.com/blogs/...)

## Norvig vs. Chomsky and the Fight for the Future of AI

KEVIN GOLD

When the Director of Research for Google compares one of the most highly regarded linguists of all time to Bill O'Reilly, you know it is *on*. Recently, Peter Norvig, Google's Director of Research and co-author of [the most popular artificial intelligence textbook in the world](#), wrote a [webpage](#) extensively criticizing Noam Chomsky, arguably the most influential linguist in the world. Their disagreement points to a revolution in artificial intelligence that, like many revolutions, threatens to destroy as much as it improves. Chomsky, one of the old guard, wishes for an elegant theory of intelligence and language that looks past human fallibility to try to see simple structure underneath. Norvig, meanwhile, represents the new philosophy: truth by statistics,

Chomsky photo by Duncan Rawlinson and his Online Photography School. Norvig photo by Peter Norvig

An interesting manifestation of this trend is the public argument between Noam Chomsky and Peter Norvig on the nature of language. Chomsky long ago proposed a hierarchical model of formal language grammars. Peter Norvig is a proponent of probabilistic models of language. Indeed all successful automated language processing systems are probabilistic.

<http://www.tor.com/blogs/2011/06/norvig-vs-chomsky-and-the-fight-for-the-future-of-ai>

# What Is MapReduce?

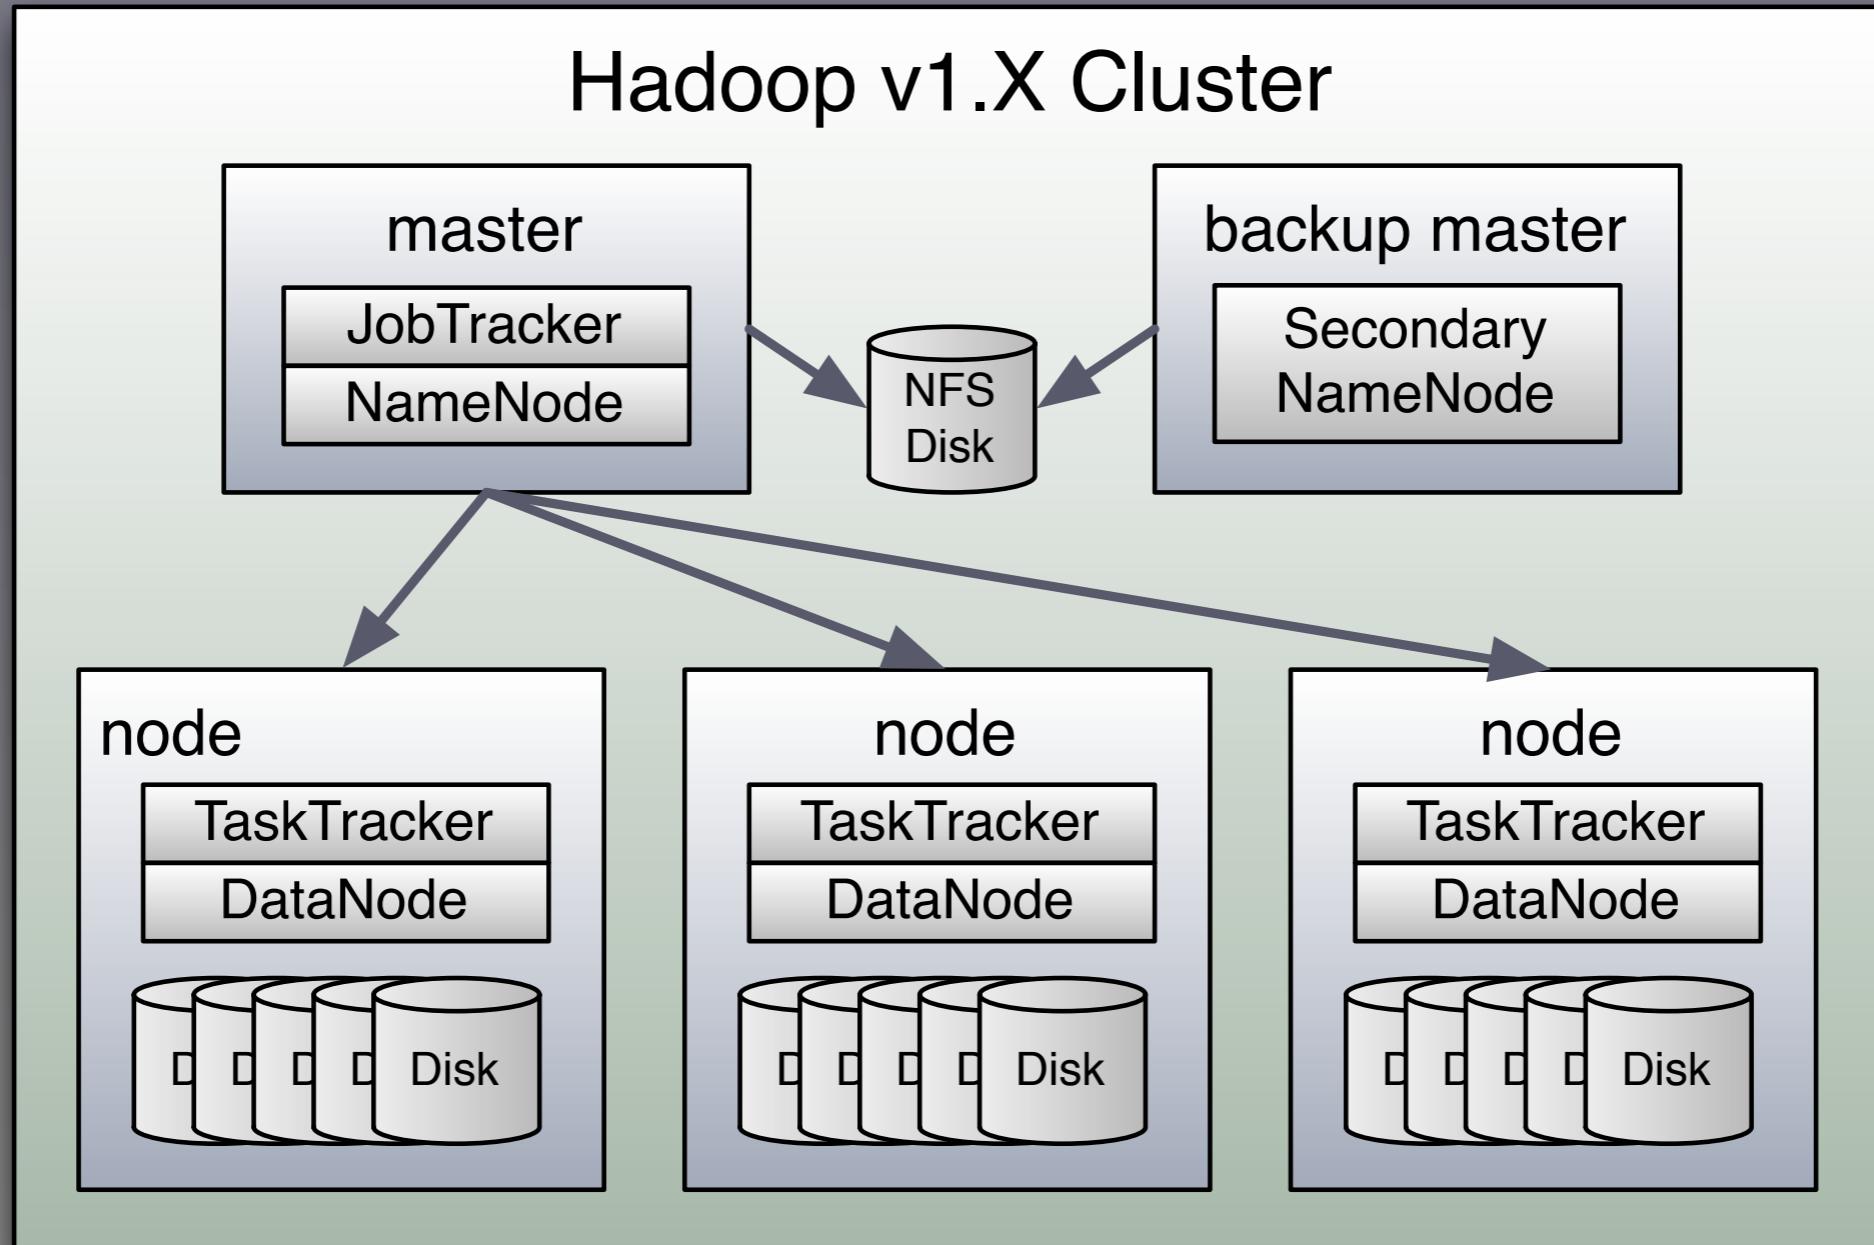

Right © 2011

Sunday, July 7, 13

“The Bean” on a sunny day – with some of my relatives ;)

Hadoop is the  
dominant copious data  
platform today.

# A Hadoop Cluster

Sunday, July 7, 13

A Hadoop v1.X cluster. (V2.X introduces changes in the master processes, including support for high-availability and federation...). In brief:  
JobTracker (JT): Master of submitted MapReduce jobs. Decomposes job into tasks (each a JVM process), often run where the “blocks” of input files are located, to minimize net IO.

NameNode (NN): HDFS (Hadoop Distributed File System) master. Knows all the metadata, like block locations. Writes updates to a shared NFS disk (in V1) for use by the Secondary NameNode.

Secondary NameNode (SNN): periodically merges in-memory HDFS metadata with update log on NFS disk to form new metadata image used when booting the NN and SNN.

TaskTracker: manages each task given to it by the JT.

DataNode: manages the actual blocks it has on the node.

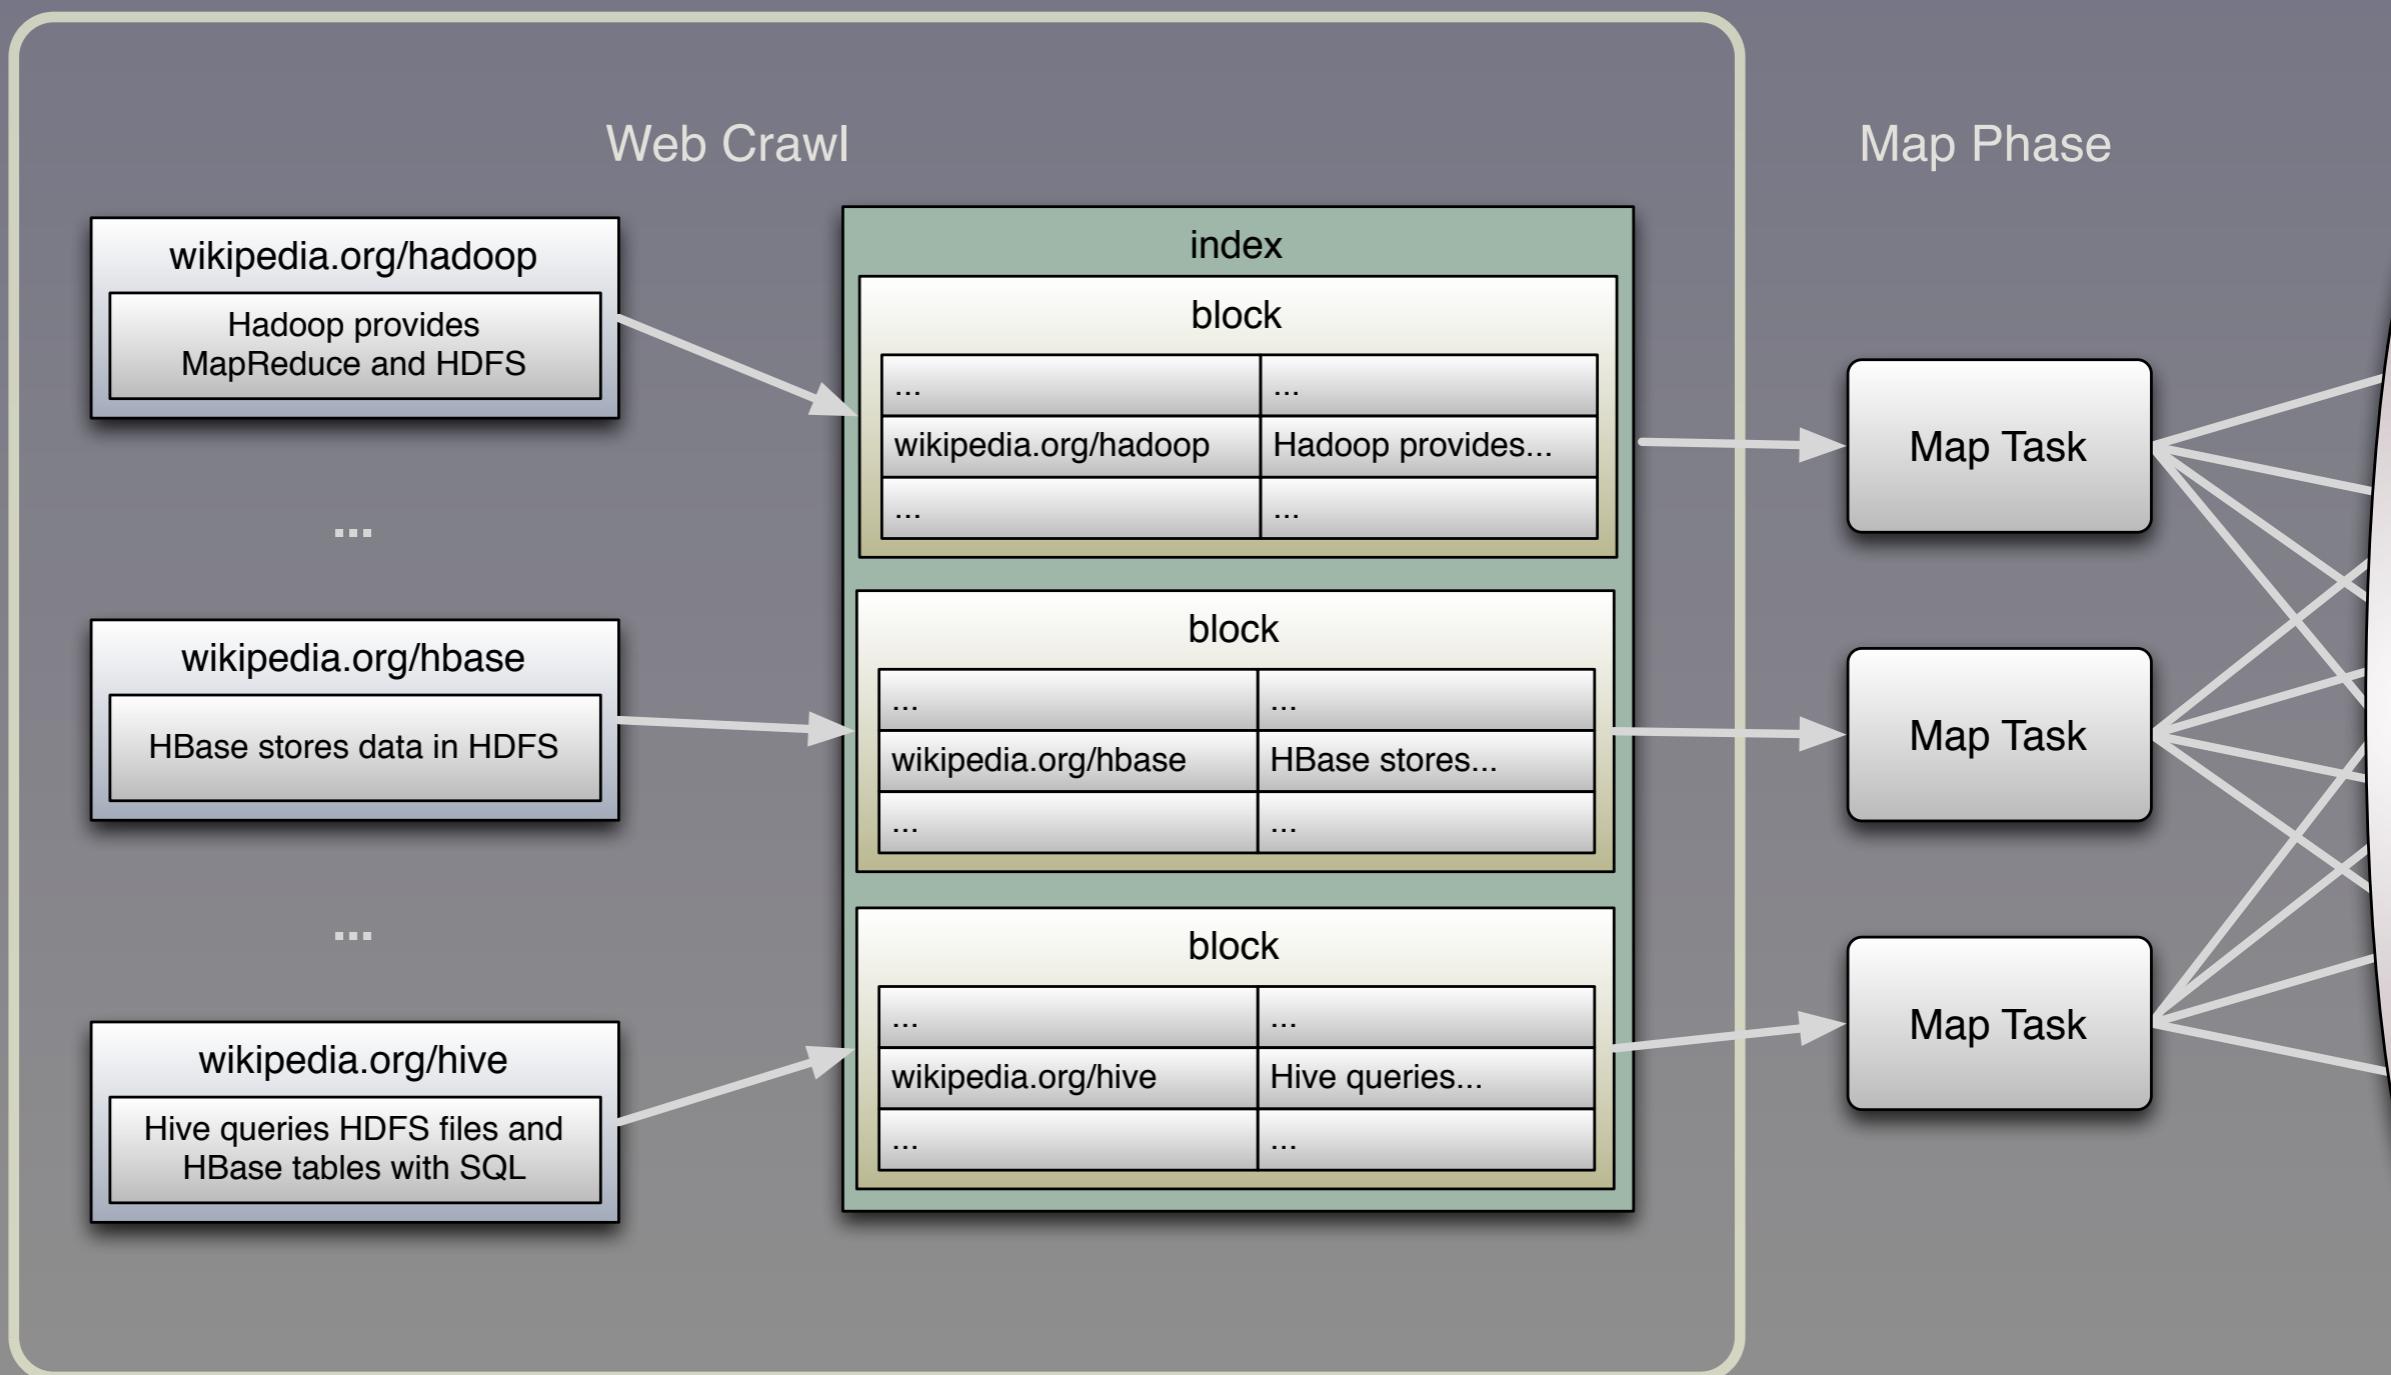

Disks: By default, Hadoop just works with “a bunch of disks” – cheaper and sometimes faster than RAID. Blocks are replicated 3x (default) so most HW failures don’t result in data loss.

# MapReduce in Hadoop

Let's look at a  
MapReduce algorithm:  
Inverted Index.

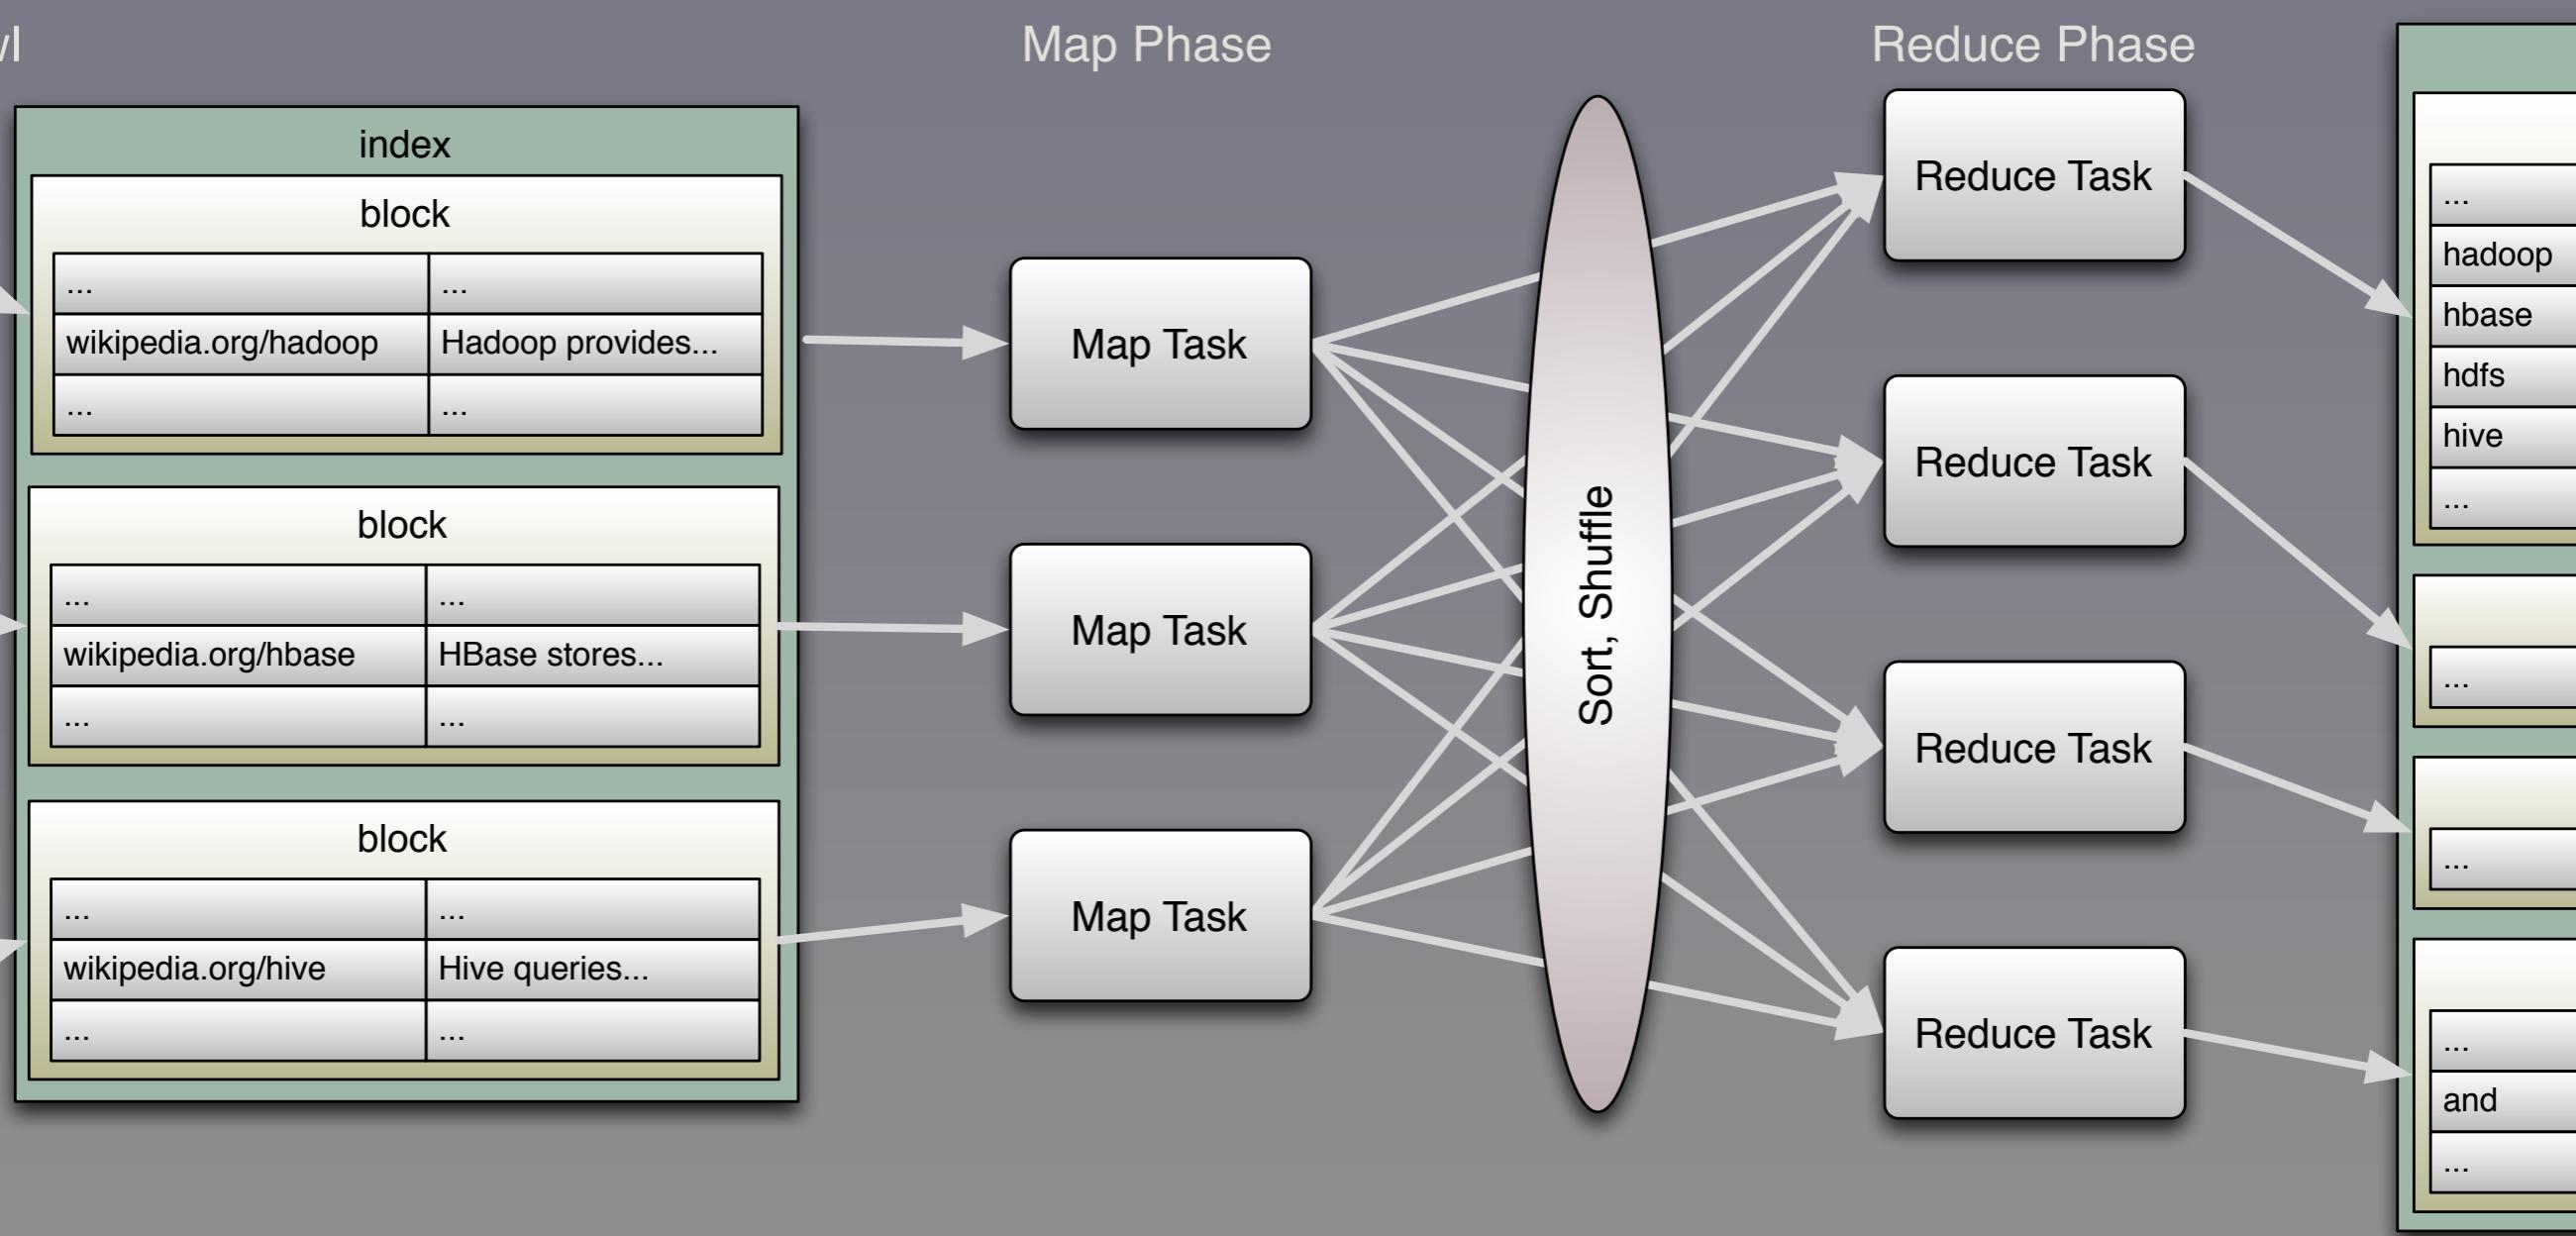

Used for text/web search.

# Crawl the Interwebs

# Compute Inverse Index

to Crawl

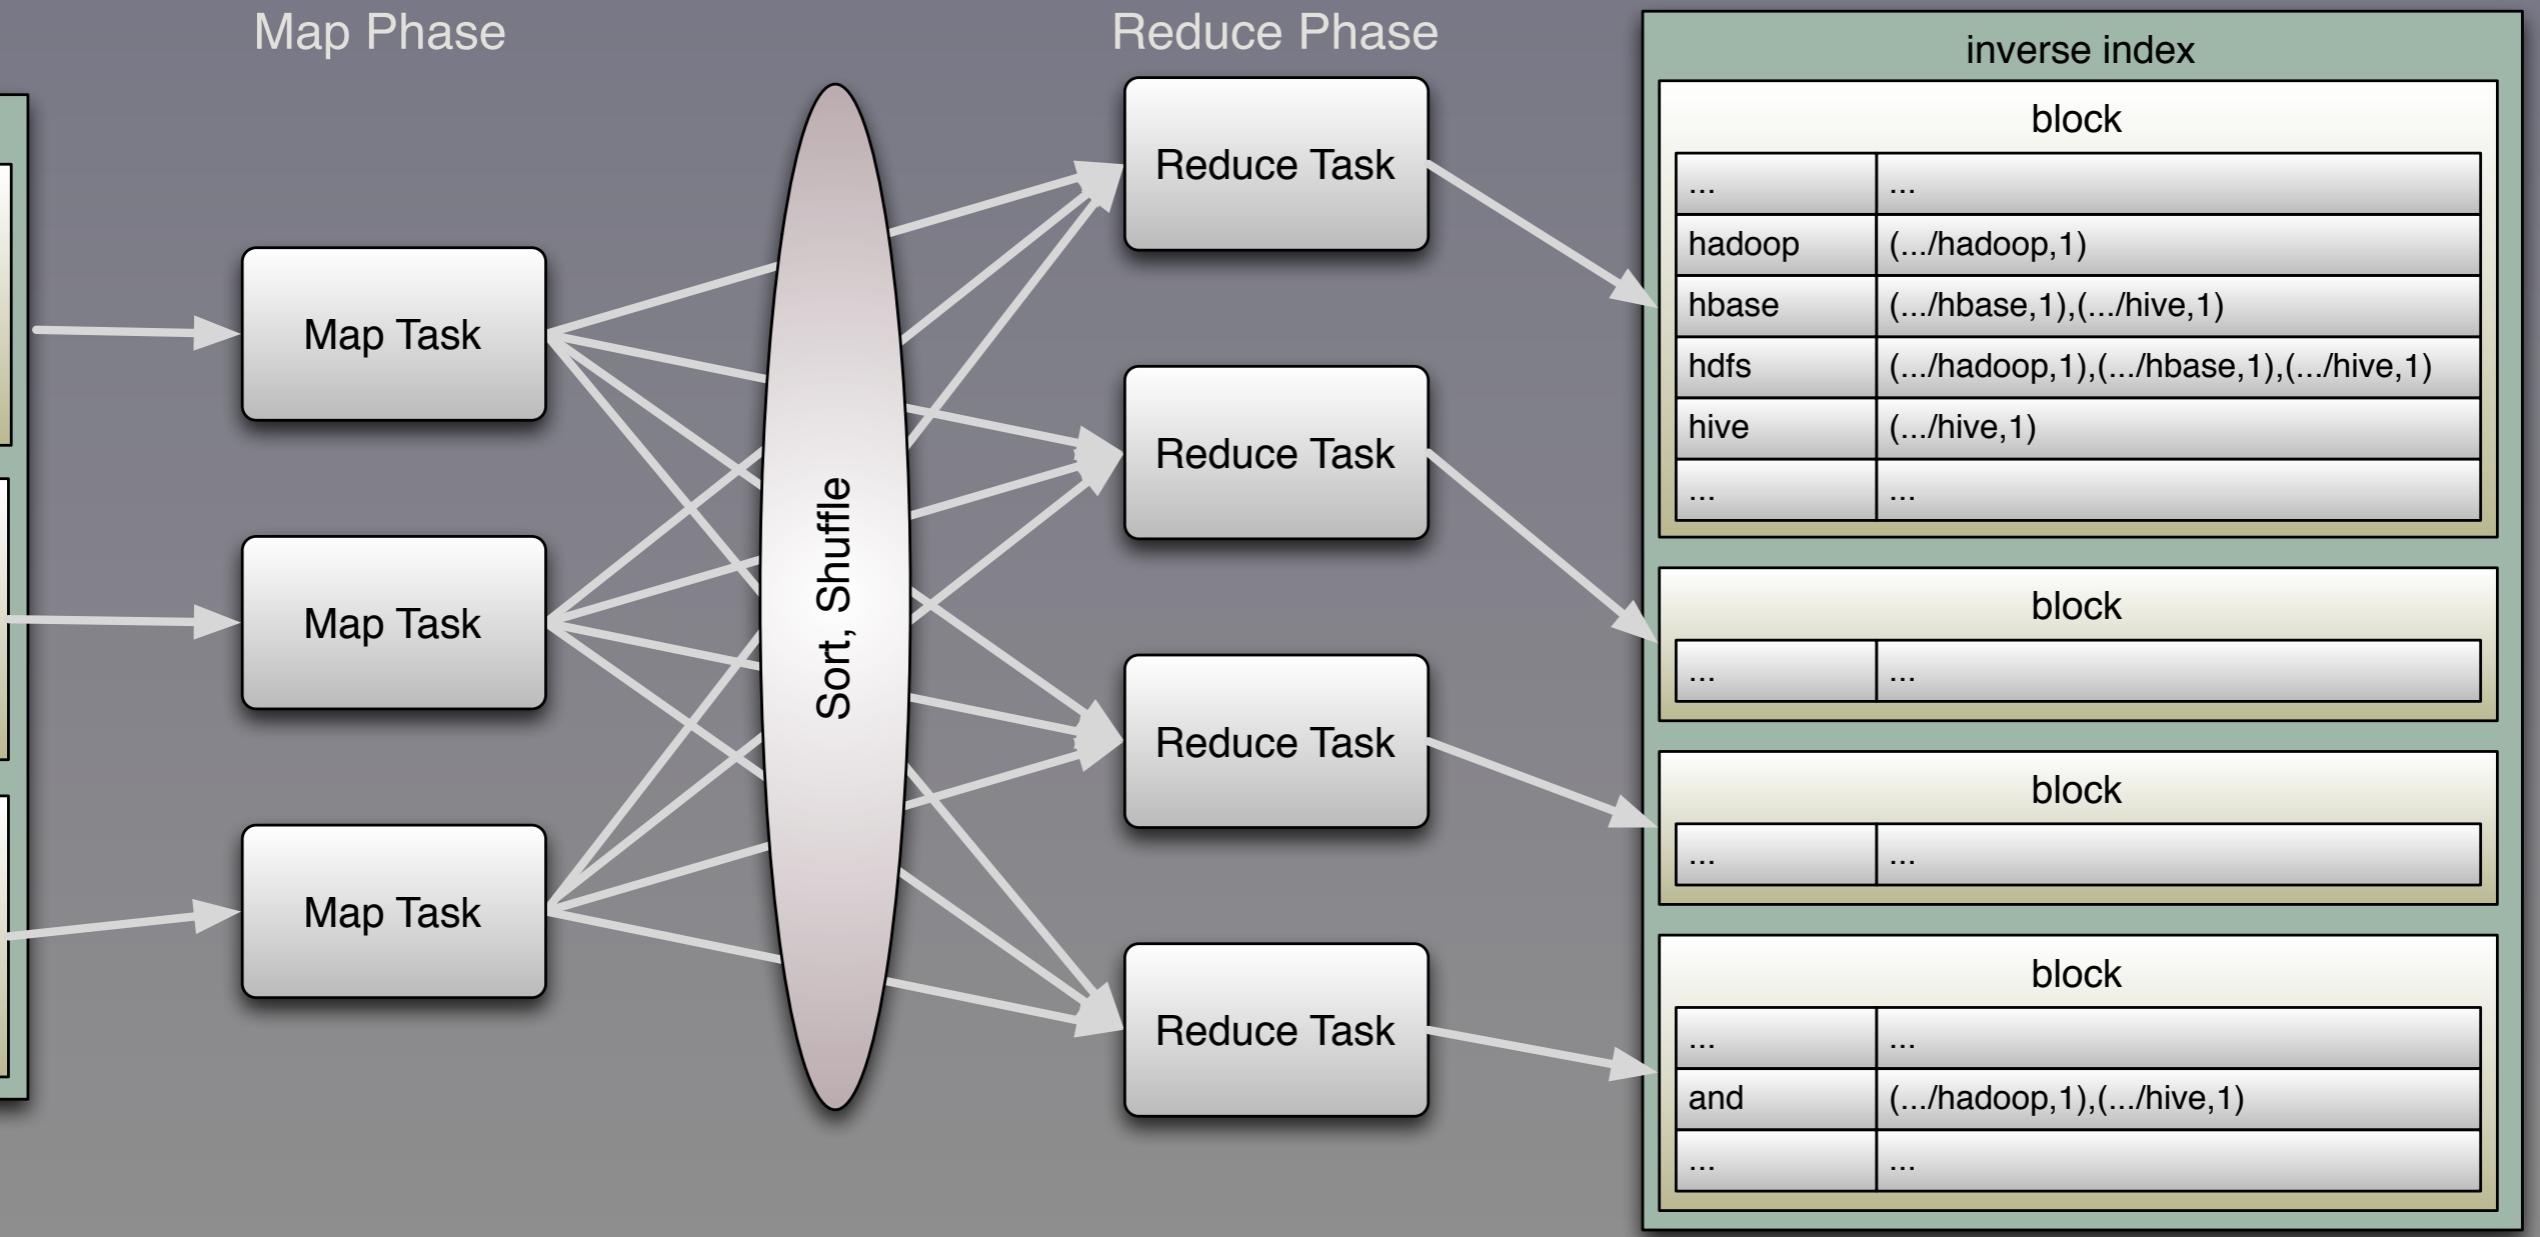

# Compute Inverse Index

Now run a MapReduce job, where a separate Map task for each input block will be started. Each map tokenizes the content in to words, counts the words, and outputs key-value pairs...

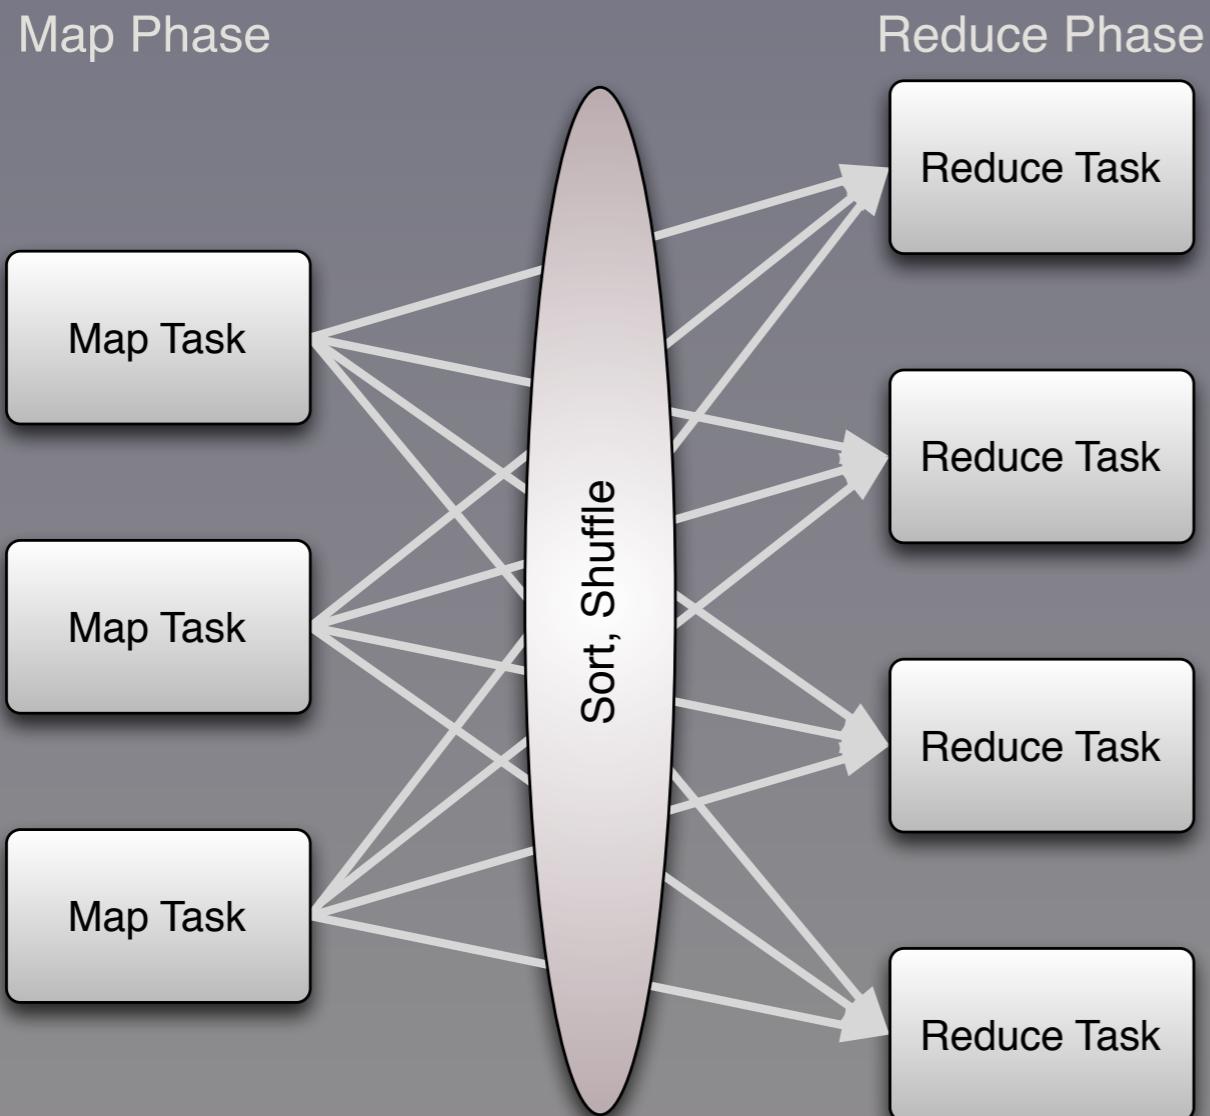

... Each key is a word that was found and the corresponding value is a tuple of the URL (or other document id) and the count of the words (or alternatively, the frequency within the document). Shown are what the first map task would output (plus other k-v pairs) for the (fake) Wikipedia "Hadoop" page. (Note that we convert to lower case...)

# Compute Inverse Index

Finally, each reducer will get some range of the keys. There are ways to control this, but we'll just assume that the first reducer got all keys starting with "h" and the last reducer got all the "and" keys. The reducer outputs each word as a key and a list of tuples consisting of the URLs (or doc ids) and the frequency/count of the word in that document, sorted by most frequent first. (All our docs have only one occurrence of any word, so the sort is moot...)

# Anatomy: MapReduce Job

*Map (or Flatmap):*

- Transform one input to 0-N outputs.

*Reduce:*

- Collect multiple inputs into one output.

**Andrew Whang**

For your consideration...

So, MapReduce is  
a mashup of our friends  
flatmap and reduce.

Today,  
Hadoop is our best,  
general-purpose tool  
for horizontal scaling  
of Copious Data.

# MapReduce and Its Discontents

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

Is MapReduce the end of the story? Does it meet all our needs? Let's look at a few problems...  
Photo: Gratuitous Romantic beach scene, Ohio St. Beach, Feb. 2011.

It's hard to *implement*  
many *Algorithms*  
in *MapReduce*.

Even word count is not “obvious”. When you get to fancier stuff like joins, group-bys, etc., the mapping from the algorithm to the implementation is not trivial at all. In fact, implementing algorithms in MR is now a specialized body of knowledge.

# MapReduce is very course-grained.

## 1-Map, 1-Reduce phase...

Even word count is not “obvious”. When you get to fancier stuff like joins, group-bys, etc., the mapping from the algorithm to the implementation is not trivial at all. In fact, implementing algorithms in MR is now a specialized body of knowledge. The Hadoop Java API is even more verbose and tedious to use than it should be.

For *Hadoop* in  
particularly,  
the *Java API* is  
*hard to use.*

Let's look at code for a simpler algorithm,  
Word Count.

Tokenize as before, but  
ignore original  
document locations.

```

import org.apache.hadoop.io.*;
import org.apache.hadoop.mapred.*;
import java.util.StringTokenizer;

class WCMapper extends MapReduceBase
    implements Mapper<LongWritable, Text, Text, IntWritable> {

    static final IntWritable one = new IntWritable(1);
    static final Text word = new Text(); // Value will be set in a non-thread-safe way!

    @Override
    public void map(LongWritable key, Text valueDocContents,
                    OutputCollector<Text, IntWritable> output, Reporter reporter) {
        String[] tokens = valueDocContents.toString.split("\\s+");
        for (String wordString: tokens) {
            if (wordString.length > 0) {
                word.set(wordString.toLowerCase());
                output.collect(word, one);
            }
        }
    }
}

class Reduce extends MapReduceBase
    implements Reducer[Text, IntWritable, Text, IntWritable] {

    public void reduce(Text keyword, java.util.Iterator<IntWritable> valuesCounts,
                      OutputCollector<Text, IntWritable> output, Reporter reporter) {
        int totalCount = 0;
        while (valuesCounts.hasNext()) {
            totalCount += valuesCounts.next.get();
        }
        output.collect(keyword, new IntWritable(totalCount));
    }
}

```

The '90s called. They want their EJBs back!

This is intentionally too small to read and we're not showing the main routine, which doubles the code size. The algorithm is simple, but the framework is in your face. In the next several slides, notice which colors dominate. In this slide, it's dominated by green for types (classes), with relatively few yellow functions that implement actual operations (i.e., do actual work).

The main routine I've omitted contains boilerplate details for configuring and running the job. This is just the "core" MapReduce code. In fact, Word Count is not too bad, but when you get to more complex algorithms, even conceptually simple ideas like relational-style joins and group-bys, the corresponding MapReduce code in this API gets complex and tedious very fast!

# Use Cascading (Java)

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

Cascading is a Java library that provides higher-level abstractions for building data processing pipelines with concepts familiar from SQL such as a joins, group-bys, etc. It works on top of Hadoop's MapReduce and hides most of the boilerplate from you.

See <http://cascading.org>.

Photo: Fermi Lab Office Building, Batavia, IL.

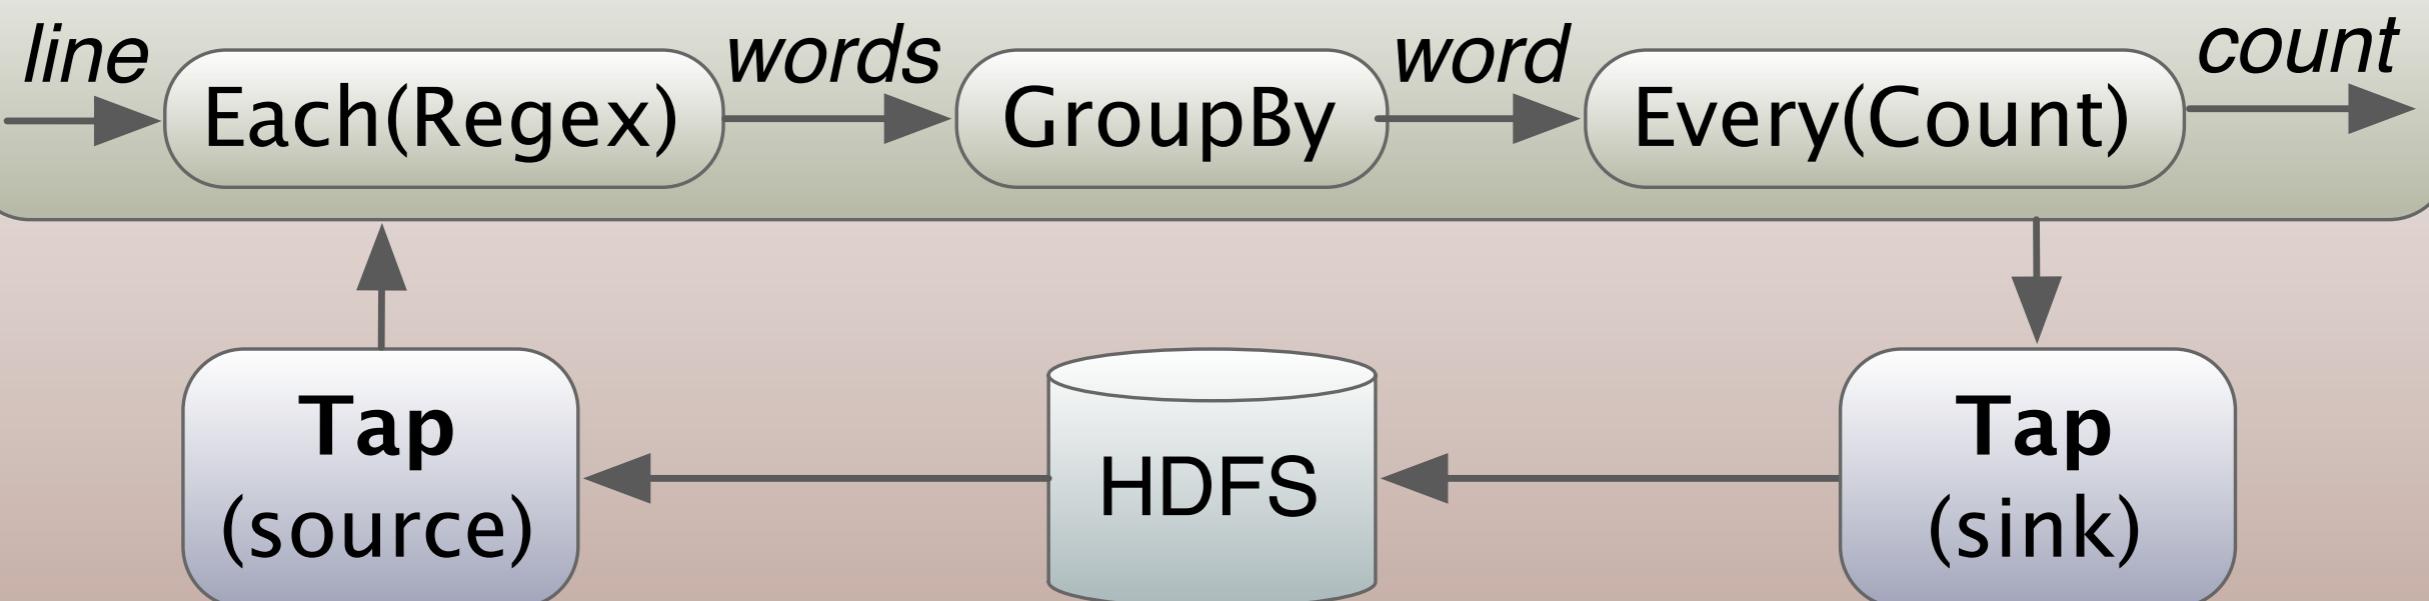

# Cascading Concepts

*Data flows consist of source and sink Taps connected by Pipes.*

# Word Count

## Flow

**Pipe ("word count assembly")**

Schematically, here is what Word Count looks like in Cascading. See <http://docs.cascading.org/cascading/1.2/userguide/html/ch02.html> for details.

```

import org.cascading.*;
...
public class WordCount {
    public static void main(String[] args) {
        String inputPath = args[0];
        String outputPath = args[1];
        Properties properties = new Properties();
        FlowConnector.setApplicationJarClass( properties, Main.class );

        Scheme sourceScheme = new TextLine( new Fields( "line" ) );
        Scheme sinkScheme = new TextLine( new Fields( "word", "count" ) );
        Tap source = new Hfs( sourceScheme, inputPath );
        Tap sink = new Hfs( sinkScheme, outputPath, SinkMode.REPLACE );

        Pipe assembly = new Pipe( "wordcount" );

        String regex = "(?<!\\pL)(?=\\pL)[^ ]*(?=<=\\pL)(?!\\pL)";
        Function function = new RegexGenerator( new Fields( "word" ), regex );
        assembly = new Each( assembly, new Fields( "line" ), function );
        assembly = new GroupBy( assembly, new Fields( "word" ) );
        Aggregator count = new Count( new Fields( "count" ) );
        assembly = new Every( assembly, count );

        FlowConnector flowConnector = new FlowConnector( properties );
        Flow flow = flowConnector.connect( "word-count", source, sink, assembly );
        flow.complete();
    }
}

```

Sunday, July 7, 13

Here is the Cascading Java code. It's cleaner than the MapReduce API, because the code is more focused on the algorithm with less boilerplate, although it looks like it's not that much shorter. HOWEVER, this is all the code, where as previously I omitted the setup (main) code. See <http://docs.cascading.org/cascading/1.2/userguide/html/ch02.html> for details of the API features used here; we won't discuss them here, but just mention some highlights.

Note that there is still a lot of green for types, but at least the API emphasizes composing behaviors together.

# Use Scalding (Scala)

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

Scalding is a Scala “DSL” (domain-specific language) that wraps Cascading providing an even more intuitive and more boilerplate-free API for writing MapReduce jobs. <https://github.com/twitter/scalding>

Scala is a new JVM language that modernizes Java’s object-oriented (OO) features and adds support for functional programming, as we discussed previously and we’ll revisit shortly.

```

import com.twitter.scalding._

class WordCountJob(args: Args) extends Job(args) {
  TextLine( args("input") )
    .read
    .flatMap('line -> 'word) {
      line: String =>
      line.trim.toLowerCase
        .split("\\\\W+")
    }
    .groupBy('word) {
      group => group.size('count)
    }
  }
  .write(Tsv(args("output")))
}

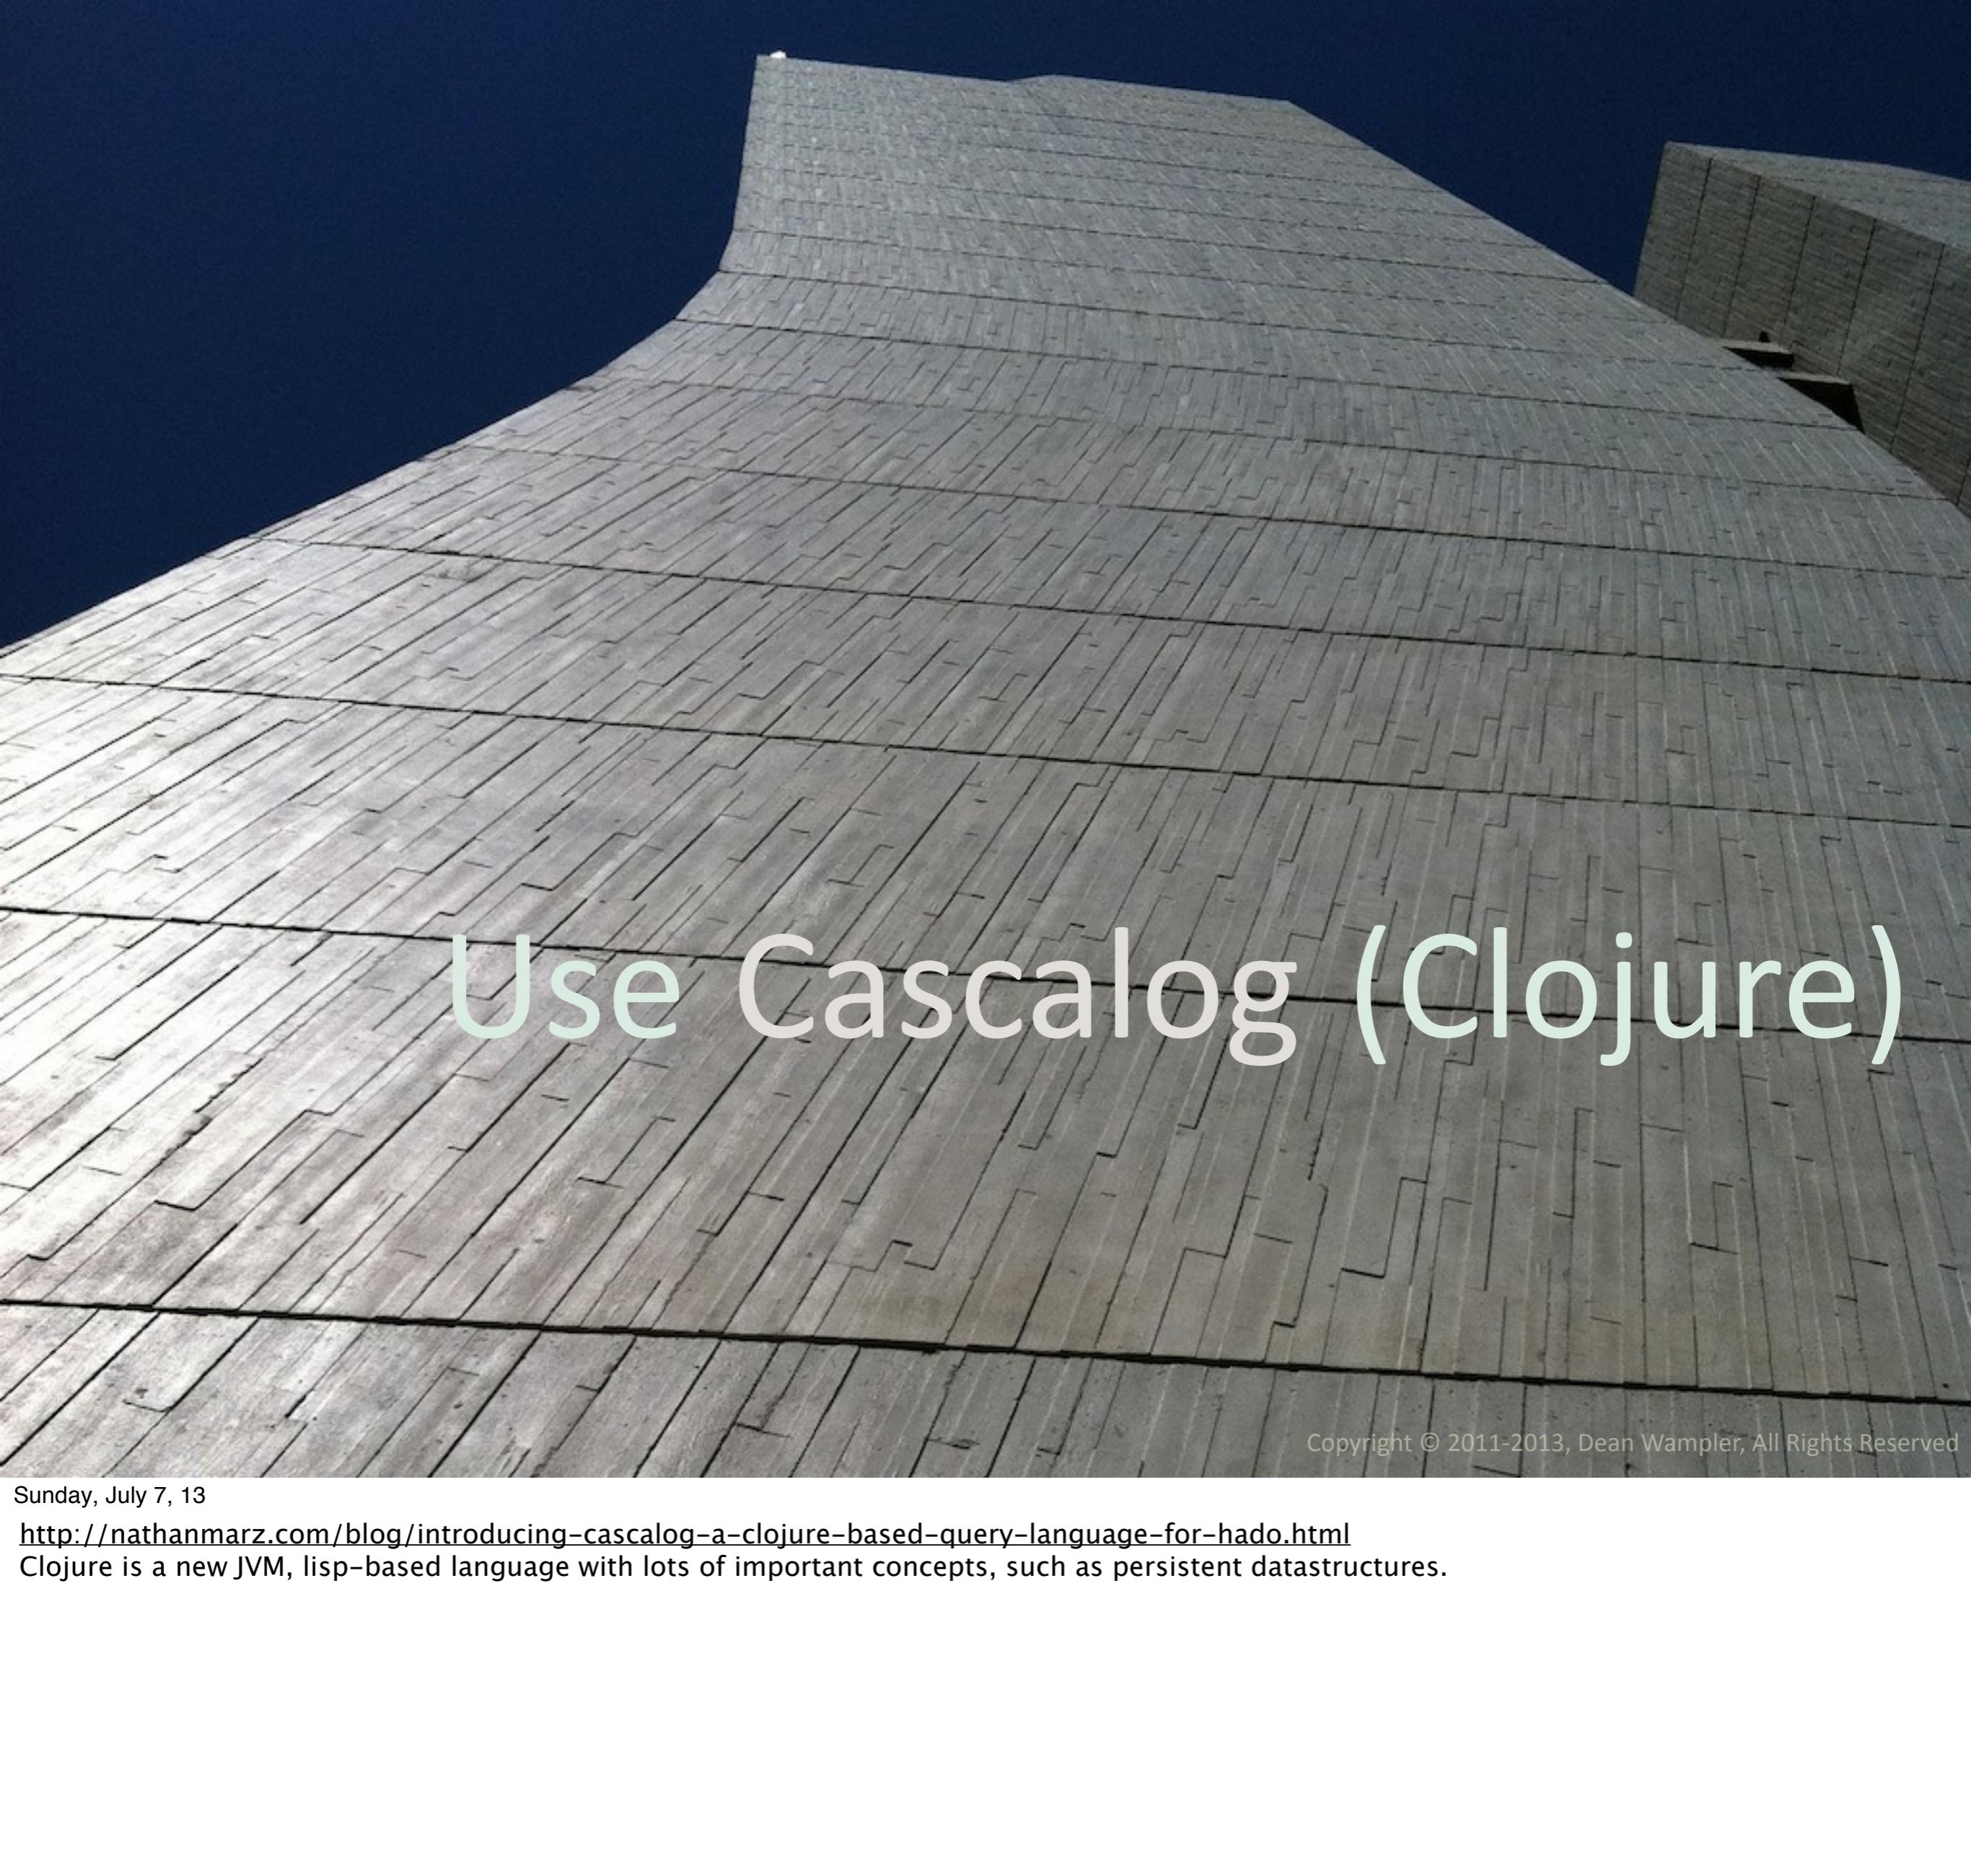

```

That's It!!

This Scala code is almost pure domain logic with very little boilerplate. There are a few minor differences in the implementation. You don't explicitly specify the "Hfs" (Hadoop Distributed File System) taps. That's handled by Scalding implicitly when you run in "non-local" mode. Also, I'm using a simpler tokenization approach here, where I split on anything that isn't a "word character" [0-9a-zA-Z\_].

There is little green, in part because Scala infers type in many cases. There is a lot more yellow for the functions that do real work!

What if MapReduce, and hence Cascading and Scalding, went obsolete tomorrow? This code is so short, I wouldn't care about throwing it away! I invested little time writing it, testing it, etc.

# Use Cascalog (Clojure)

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

<http://nathanmarz.com/blog/introducing-cascalog-a-clojure-based-query-language-for-hadoop.html>

Clojure is a new JVM, lisp-based language with lots of important concepts, such as persistent datastructures.

```
(defn lowercase [w] (.toLowerCase w))  
  
(?- (stdout) [?word ?count]  
  (sentence ?s)  
    (split ?s :> ?word1)  
    (lowercase ?word1 :> ?word)  
    (c/count ?count))
```

## Datalog-style queries

# Other Improved APIs:

- Crunch (Java) & Scrunch (Scala)
- Scoobi (Scala)
- ...

See <https://github.com/cloudera/crunch>.

Others include Scoobi (<http://nicta.github.com/scoobi/>) and Spark, which we'll discuss next.

# Use Spark (Not MapReduce)

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

<http://www.spark-project.org/>

Why isn't it more widely used? 1) lack of commercial support, 2) only recently emerged out of academia.

# Spark is a Hadoop MapReduce alternative:

- Distributed computing with in-memory caching.
- Up to 30x faster than MapReduce.
- Developed by Berkeley AMP.

# Spark is a Hadoop MapReduce alternative:

- Originally designed for machine learning applications.

```
object WordCountSpark {  
    def main(args: Array[String]) {  
        val file = spark.textFile(args(0))  
        val counts = file.flatMap(  
            line => line.split("\\W+"))  
            .map(word => (word, 1))  
            .reduceByKey(_ + _)  
        counts.saveAsTextFile(args(1))  
    }  
}
```

Also small and concise!

Use SQL!  
Hive, Shark,  
Impala, or Lingual

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

Using SQL when you can! Here are 4 options.

# Use SQL when you can!

- Hive: SQL on top of MapReduce.
- Shark: Hive ported to Spark.
- Impala: HiveQL with new, faster back end.
- Lingual: ANSI SQL on Cascading.

See <http://hive.apache.org/> or my book for Hive, <http://shark.cs.berkeley.edu/> for shark, and <http://www.cloudera.com/content/cloudera/en/products/cloudera-enterprise-core/cloudera-enterprise-RTQ.html> for Impala. Impala is very new. It doesn't yet support all Hive features.

# Word Count in Hive SQL!

```
CREATE TABLE docs (line STRING);
LOAD DATA INPATH '/path/to/docs'
INTO TABLE docs;
```

```
CREATE TABLE word_counts AS
SELECT word, count(1) AS count FROM
(SELECT explode(split(line, '\W+'))
 AS word FROM docs) w
GROUP BY word
ORDER BY word;
```

Works for Hive, Shark, and Impala

# Combinators

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

Photo: The defunct Esquire movie theater on Oak St., off the Magnificent Mile.

Why were the  
*Scala, Clojure, and SQL*  
solutions so *concise*  
and *appealing*??

Data problems  
are fundamentally  
Mathematics!

# Category Theory

- Monads - Structure.
- Abstracting over collections.
- Control flow.

Monads generalize the properties of containers, like lists and maps, such as applying a function to each element and returning a new instance of the same container type. This also applies to encapsulations of state transformations and “principled mutability”, as used in Haskell.

# Category Theory

- Monoids, Groups, Rings, etc.
- Abstracting over addition, subtraction, multiplication, and division.

# Linear Algebra

- Eigenvector and Singular Value Decomposition.
- Essential tools in machine learning.

# Set Theory and First-Order Logic

- The Relational Model.
- Data organized into tuples, grouped by relations.
- Declarative.
- Well-defined operations.

Formulated by Codd in '69. Most systems don't follow it exactly, like allowing identical records, where set elements are unique. Codd's original model didn't support NULLs either ("unknown"), but he later proposed a revision to allow them.

# Set Theory and First-Order Logic

- The Relational Model.
- Most RDBMSs deviate from RM.

Formulated by Codd in '69. Most systems don't follow it exactly, like allowing identical records, where set elements are unique. Codd's original model didn't support NULLs either ("unknown"), but he later proposed a revision to allow them.

Let's look at  
3 relational operators  
and the corresponding  
functional combinators.

# Recall our Word Counts:

```
CREATE TABLE word_counts (
  word    CHARACTER(64),
  count   INTEGER);
```

ANSI SQL syntax

# Restrict

```
SELECT * FROM word_counts  
WHERE word = 'Chicago';
```

vs.

```
word_counts.filter {  
  case (word, count) =>  
    word == "Chicago"  
}
```

(Scala)

# Project

SELECT word FROM word\_counts;

vs.

```
word_counts.map {  
    case (word, count) =>  
        word  
}
```

# Join

```
CREATE TABLE dictionary (
    word      CHARACTER(64),
    definition CHARACTER(256));
```

Table for join examples.

# Join - SQL

```
SELECT w.word, d.definition  
FROM   word_counts AS w  
       dictionary AS d  
WHERE  w.word = d.word;
```

# Join - Scalding

```
val word_counts =  
  Csv("/path...", ('wword, 'count)).read  
val definitions =  
  Csv("/path...", ('dword, 'definition)).read  
word_counts  
.joinWithLarger('wword -> 'dword,  
  dictionary)  
.project('wword, 'definition)
```

# Join

```
SELECT w.word, d.definition  
FROM   word_counts AS w  
        dictionary AS d  
WHERE  w.word = d.word;
```

vs.

```
...  
word_counts  
  .joinWithTiny('wword' -> 'dword,  
                 dictionary)  
  .project('wword', 'definition')
```

Joins are expensive.  
Your data system needs  
to exploit  
optimizations...

We could go on, but  
you get the point.

Declarative, functional  
combinators are a  
natural tool for data.

# SQL vs. FP

- SQL
  - Lots of optimizations for data manipulation.
- FP
  - Functions are first class!

A drawback of SQL is that it doesn't provide first class functions, so (depending on the system) you're limited to those that are built-in or UDFs (user-defined funcs) that you can write and add. FP languages make this easy!!

# FP to the Rescue!

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

# Popular Claim:

*Multicore concurrency*  
is driving FP adoption.

My Claim:  
*Data will drive  
widespread FP  
adoption.*

Even today, most developers get by without understanding concurrency. Many will just use an Actor or Reactive model to “solve” their problems. I think more devs will have to learn how to work with data at scale and that fact will drive them to FP.

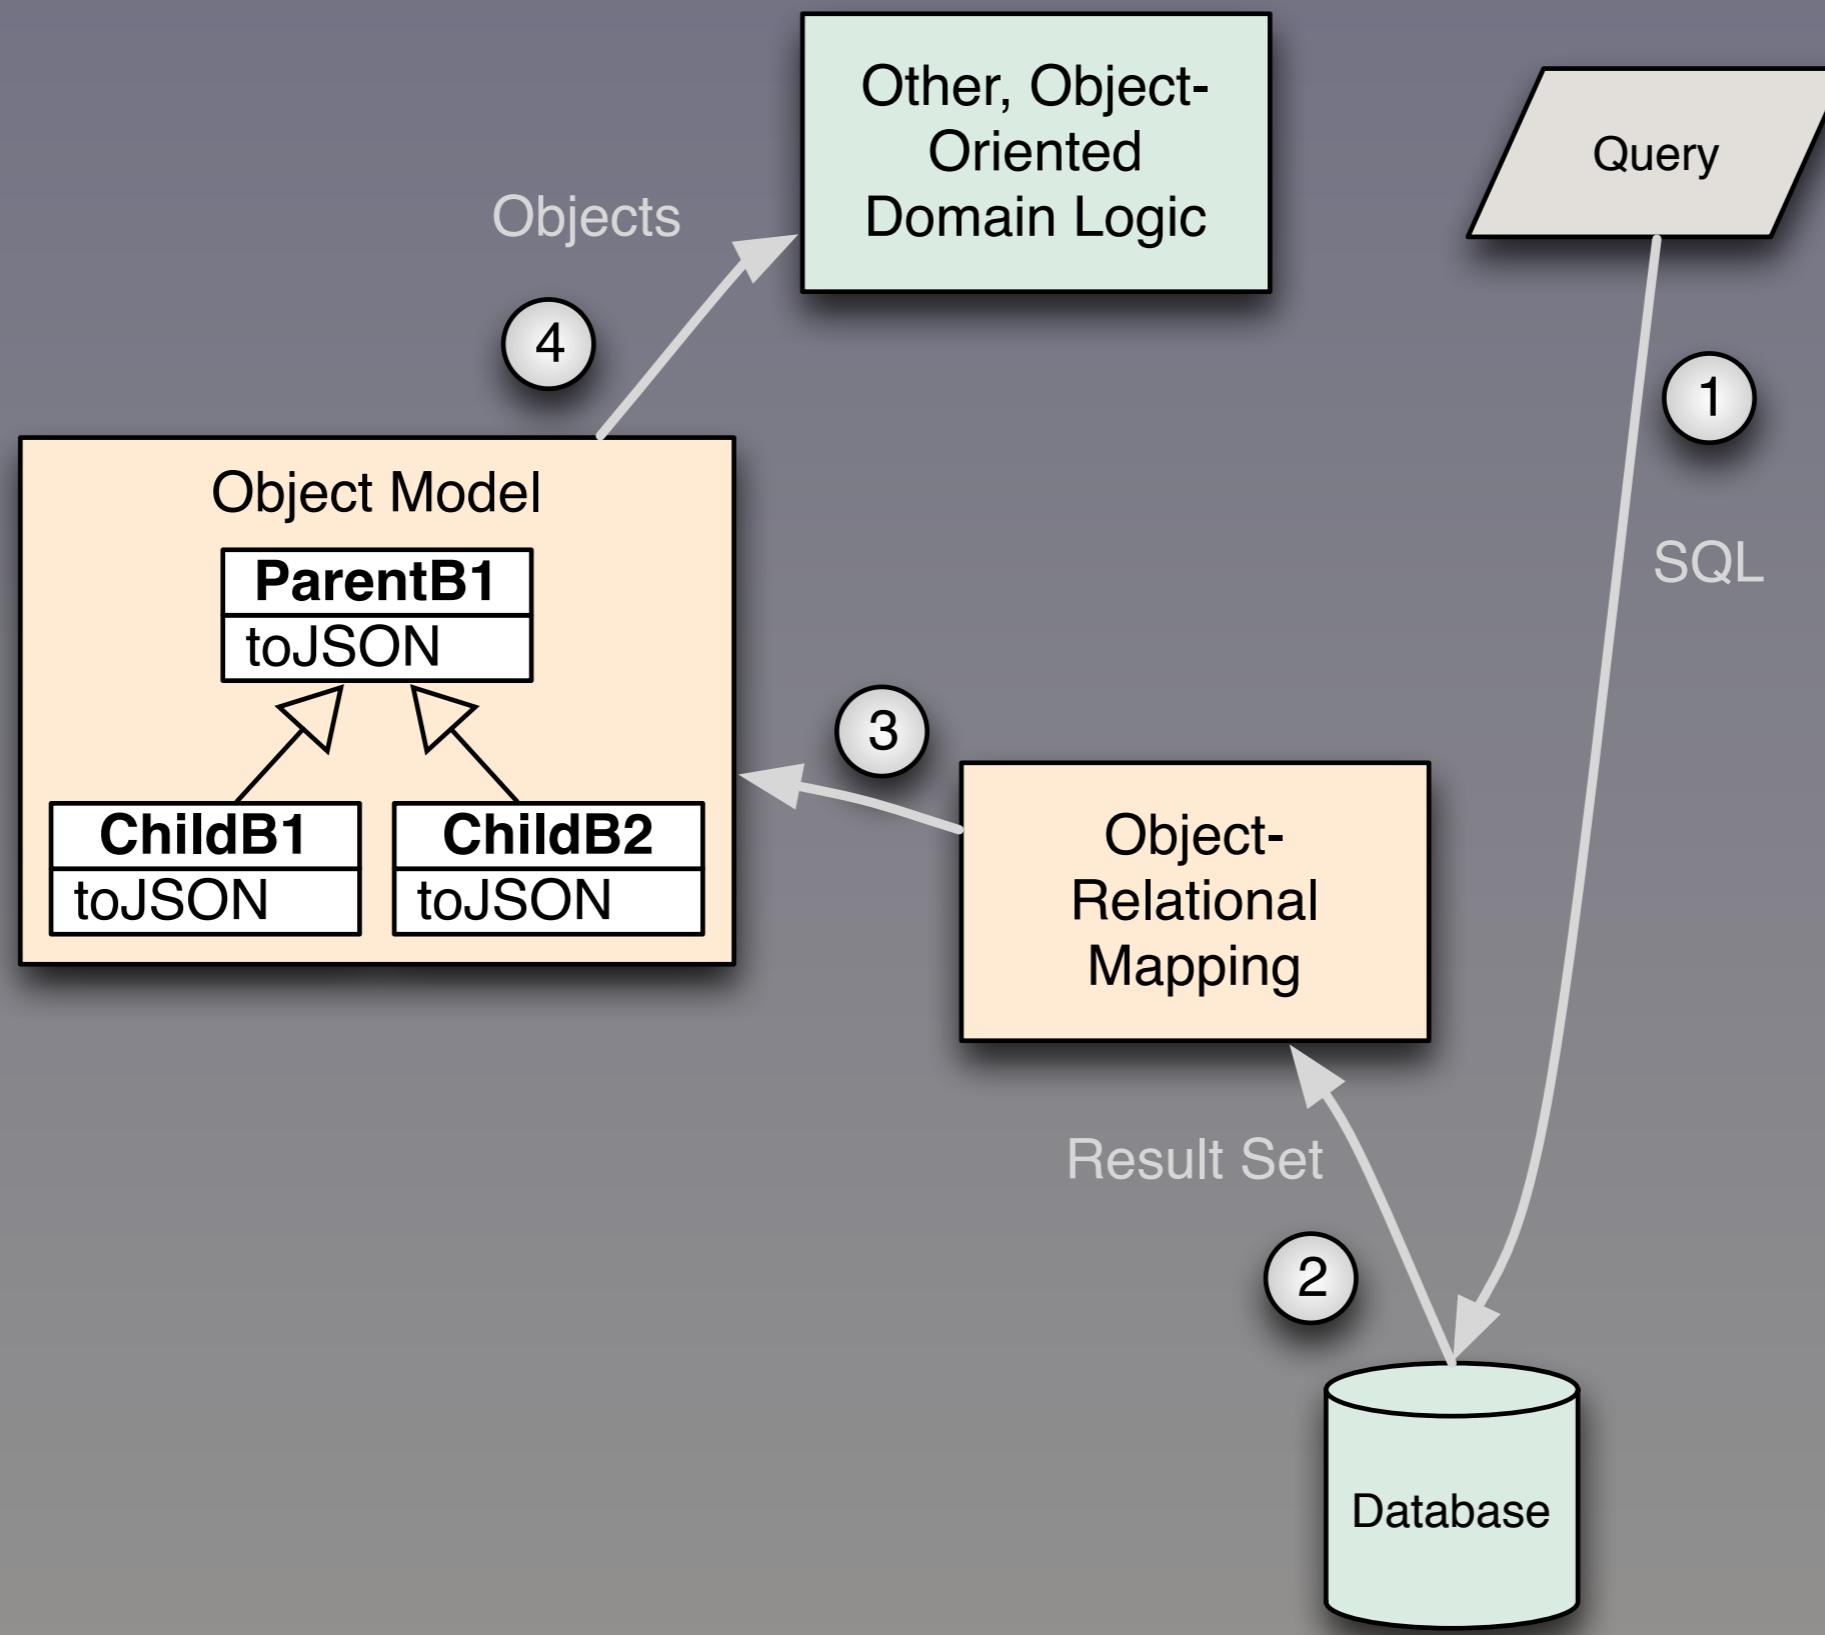

# Data Architectures

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

What should software architectures look like for these kinds of systems?

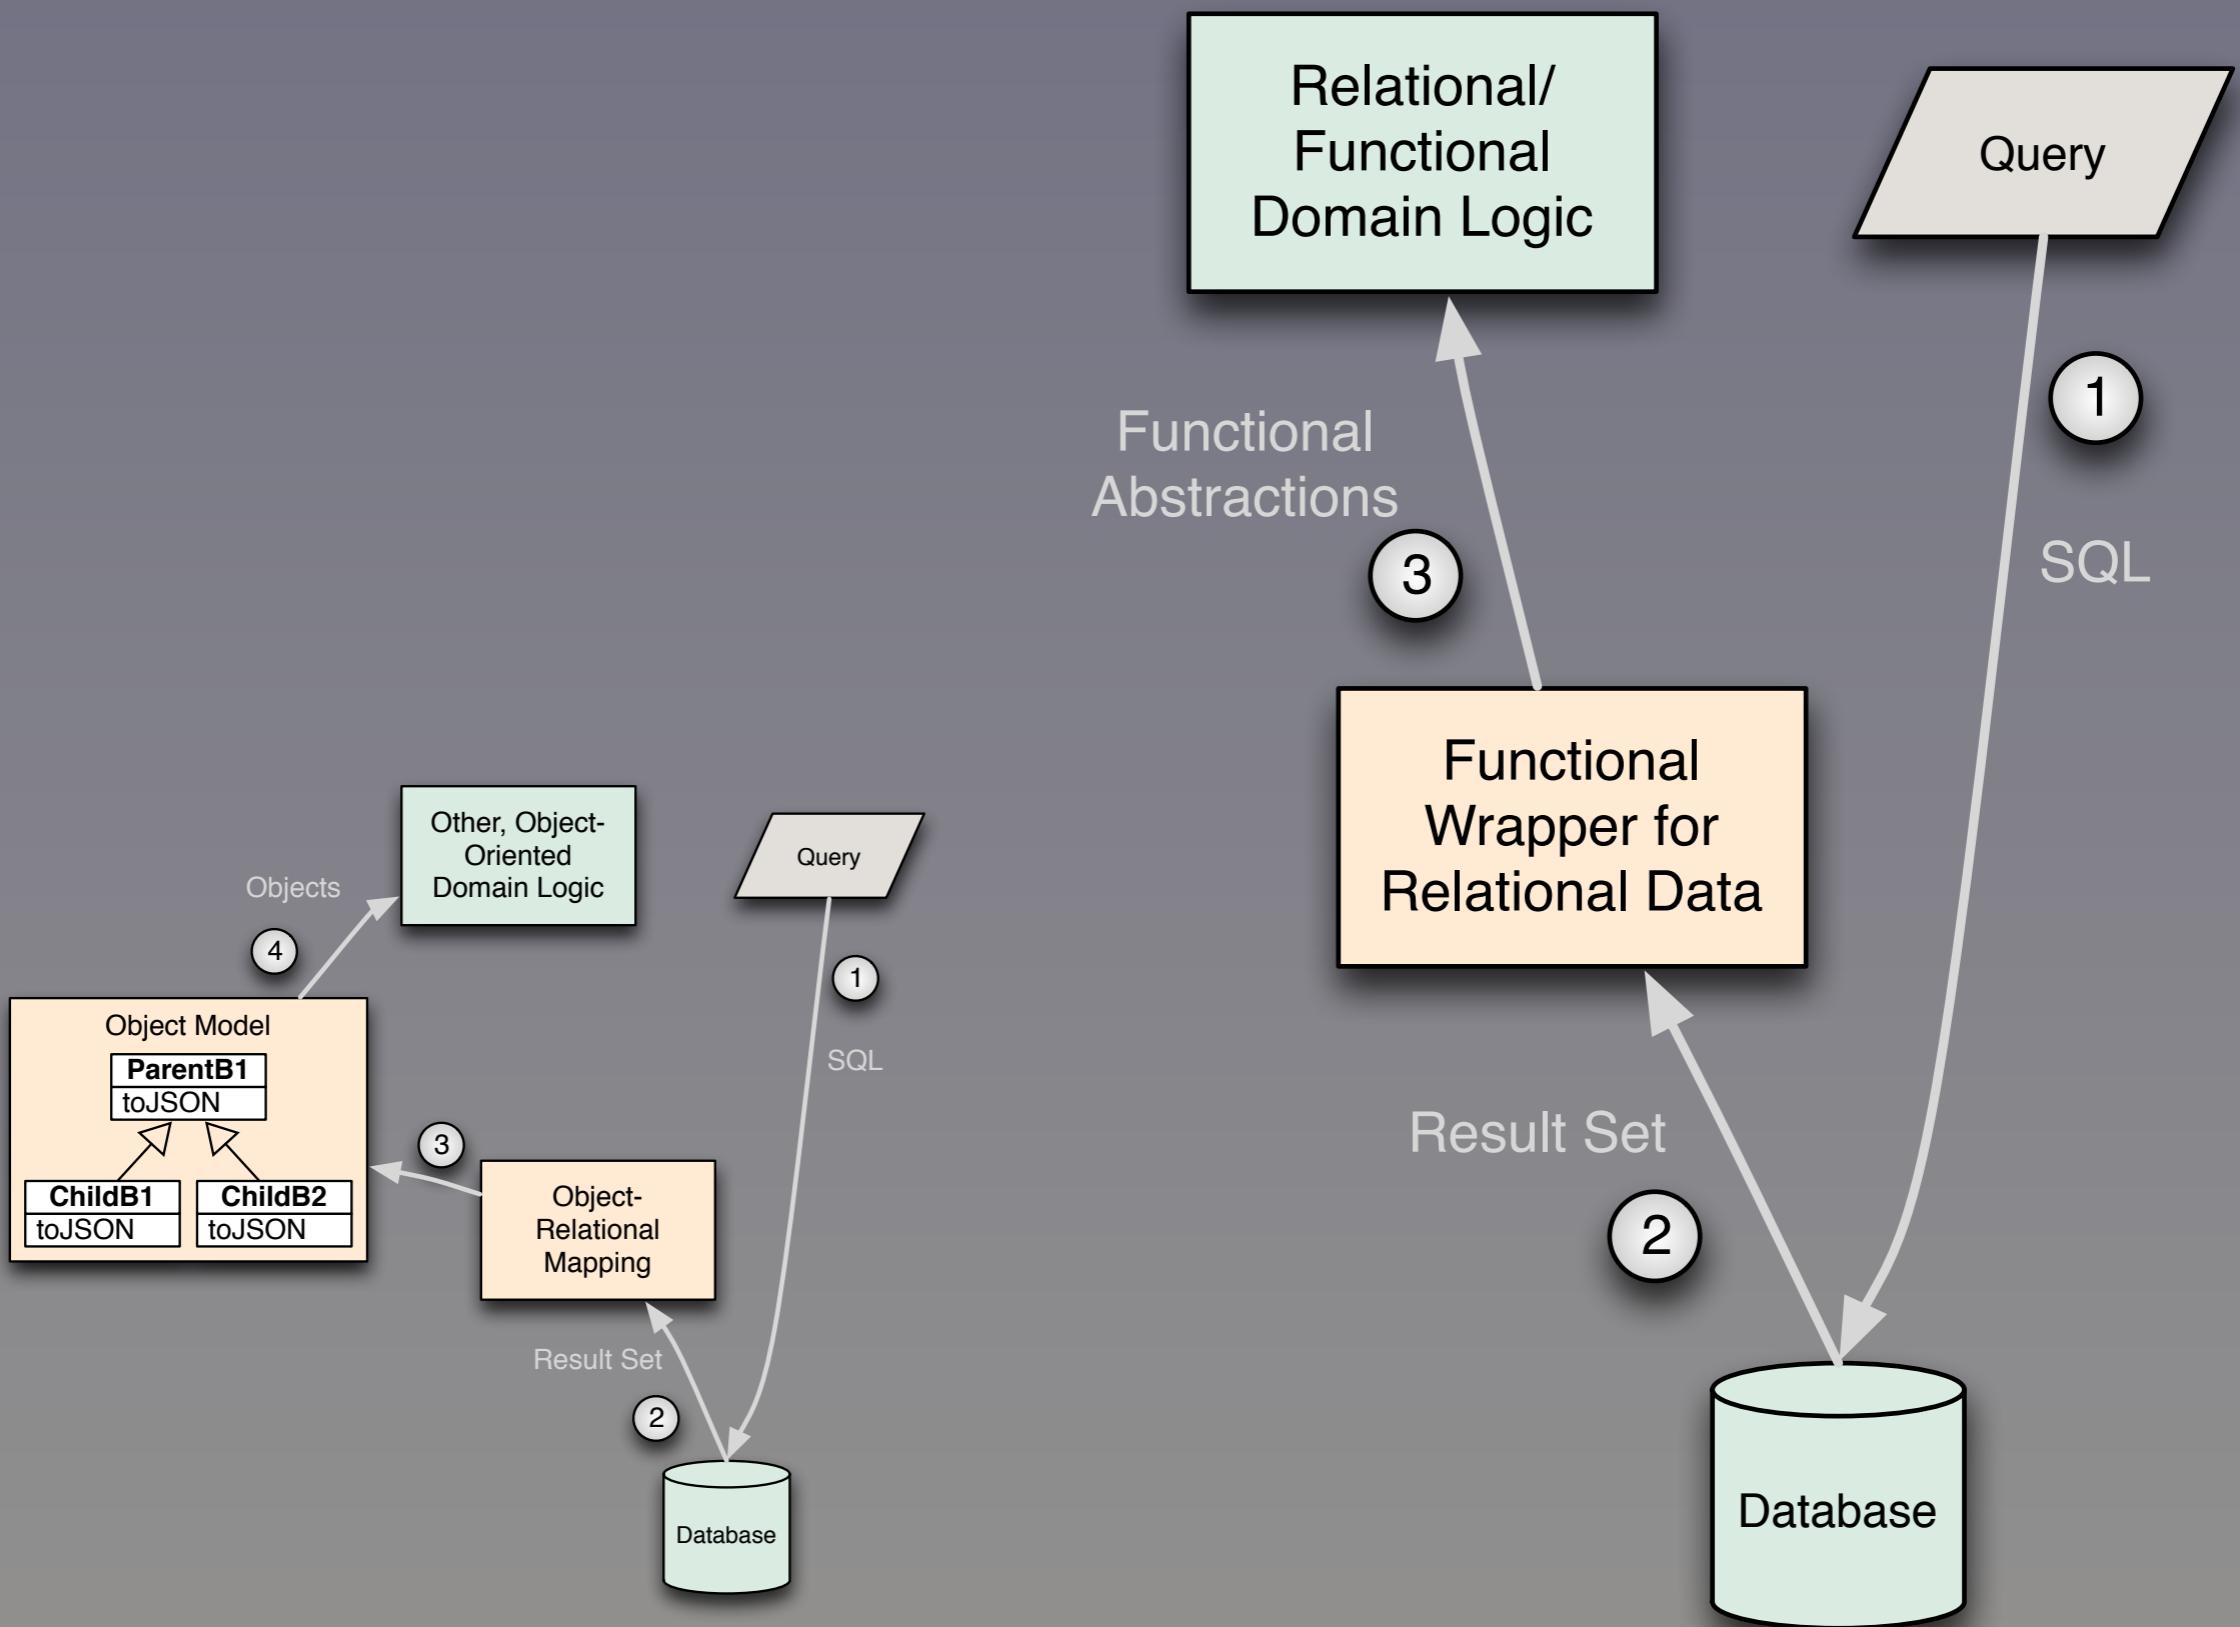

Photo: Two famous 19th Century Buildings in Chicago.

Sunday, July 7, 13

Traditionally, we've kept a rich, in-memory domain model requiring an ORM to convert persistent data into the model. This is resource overhead and complexity we can't afford in big data systems. Rather, we should treat the result set as it is, a particular kind of collection, do the minimal transformation required to exploit our collections libraries and classes representing some domain concepts (e.g., Address, StockOption, etc.), then write functional code to implement business logic (or drive emergent behavior with machine learning algorithms...)

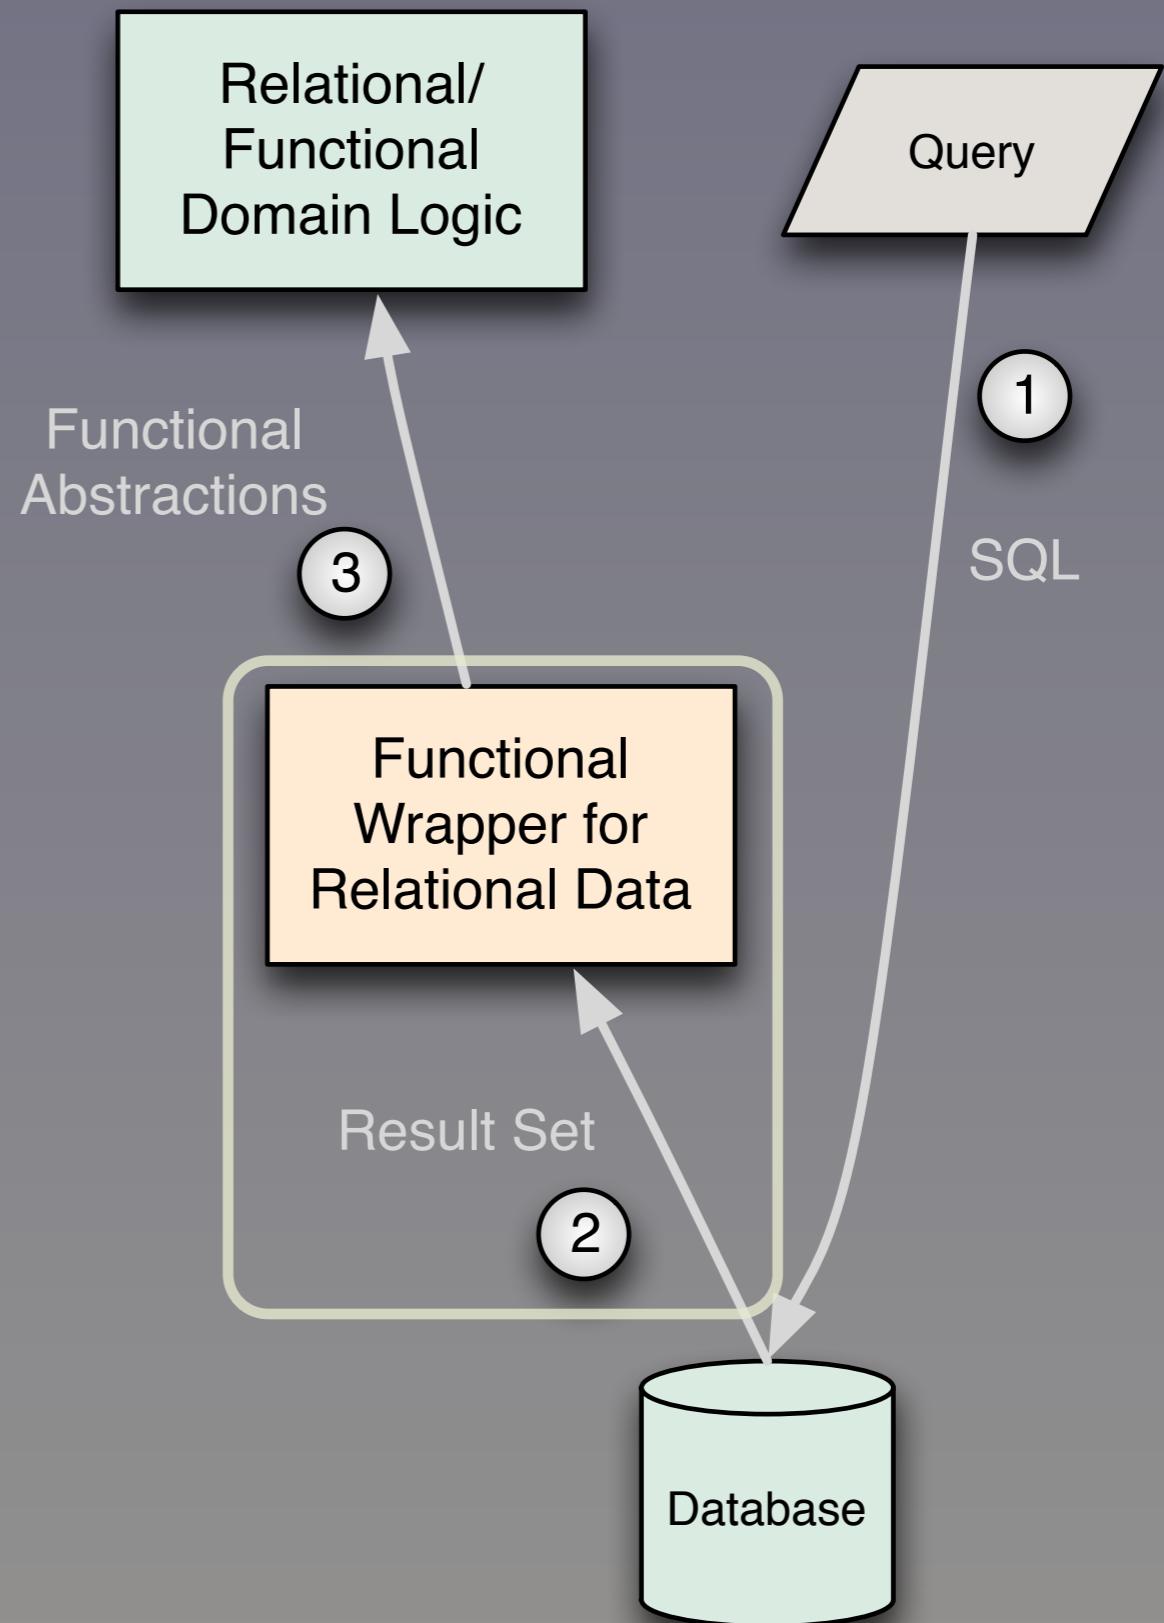

The `toJSON` methods are there because we often convert these object graphs back into fundamental structures, such as the maps and arrays of JSON so we can send them to the browser!

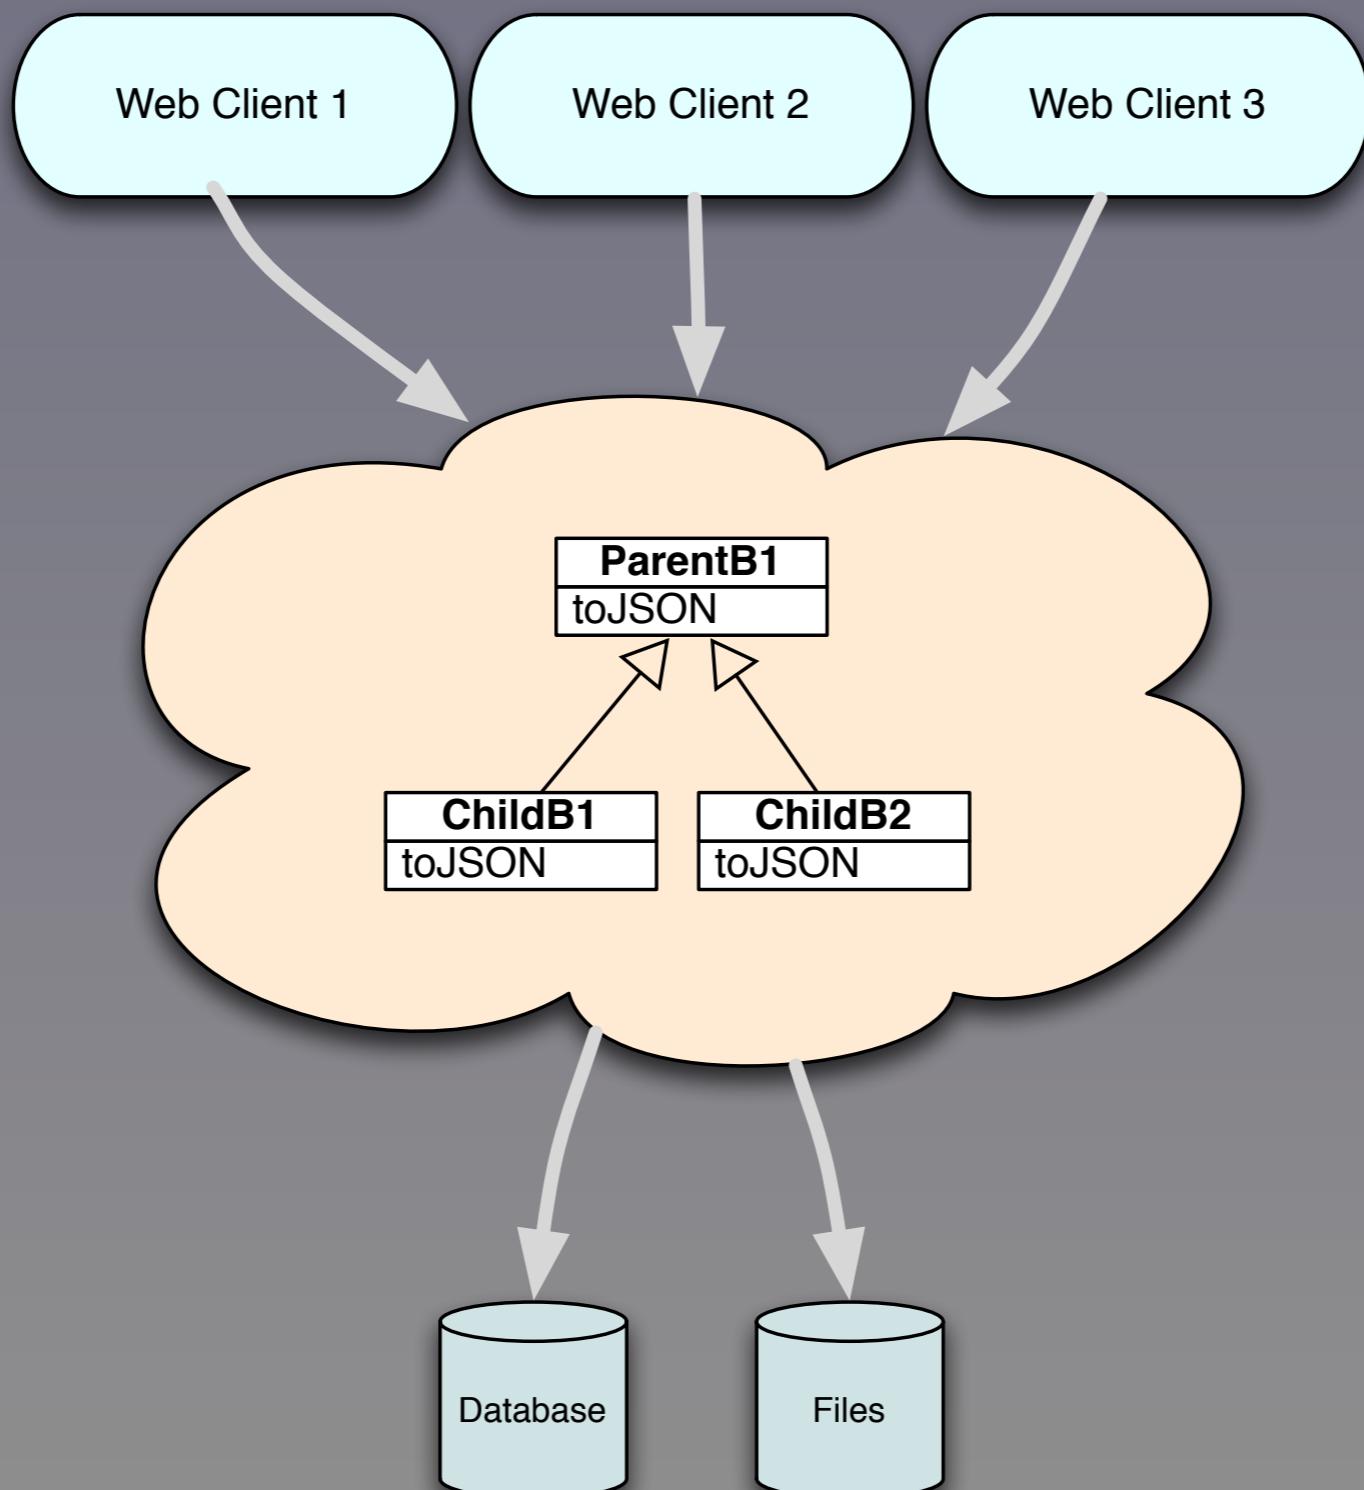

But the traditional systems are a poor fit for this new world: 1) they add too much overhead in computation (the ORM layer, etc.) and memory (to store the objects). Most of what we do with data is mathematical transformation, so we're far more productive (and runtime efficient) if we embrace fundamental data structures used throughout (lists, sets, maps, trees) and build rich transformations into those libraries, transformations that are composable to implement business logic.

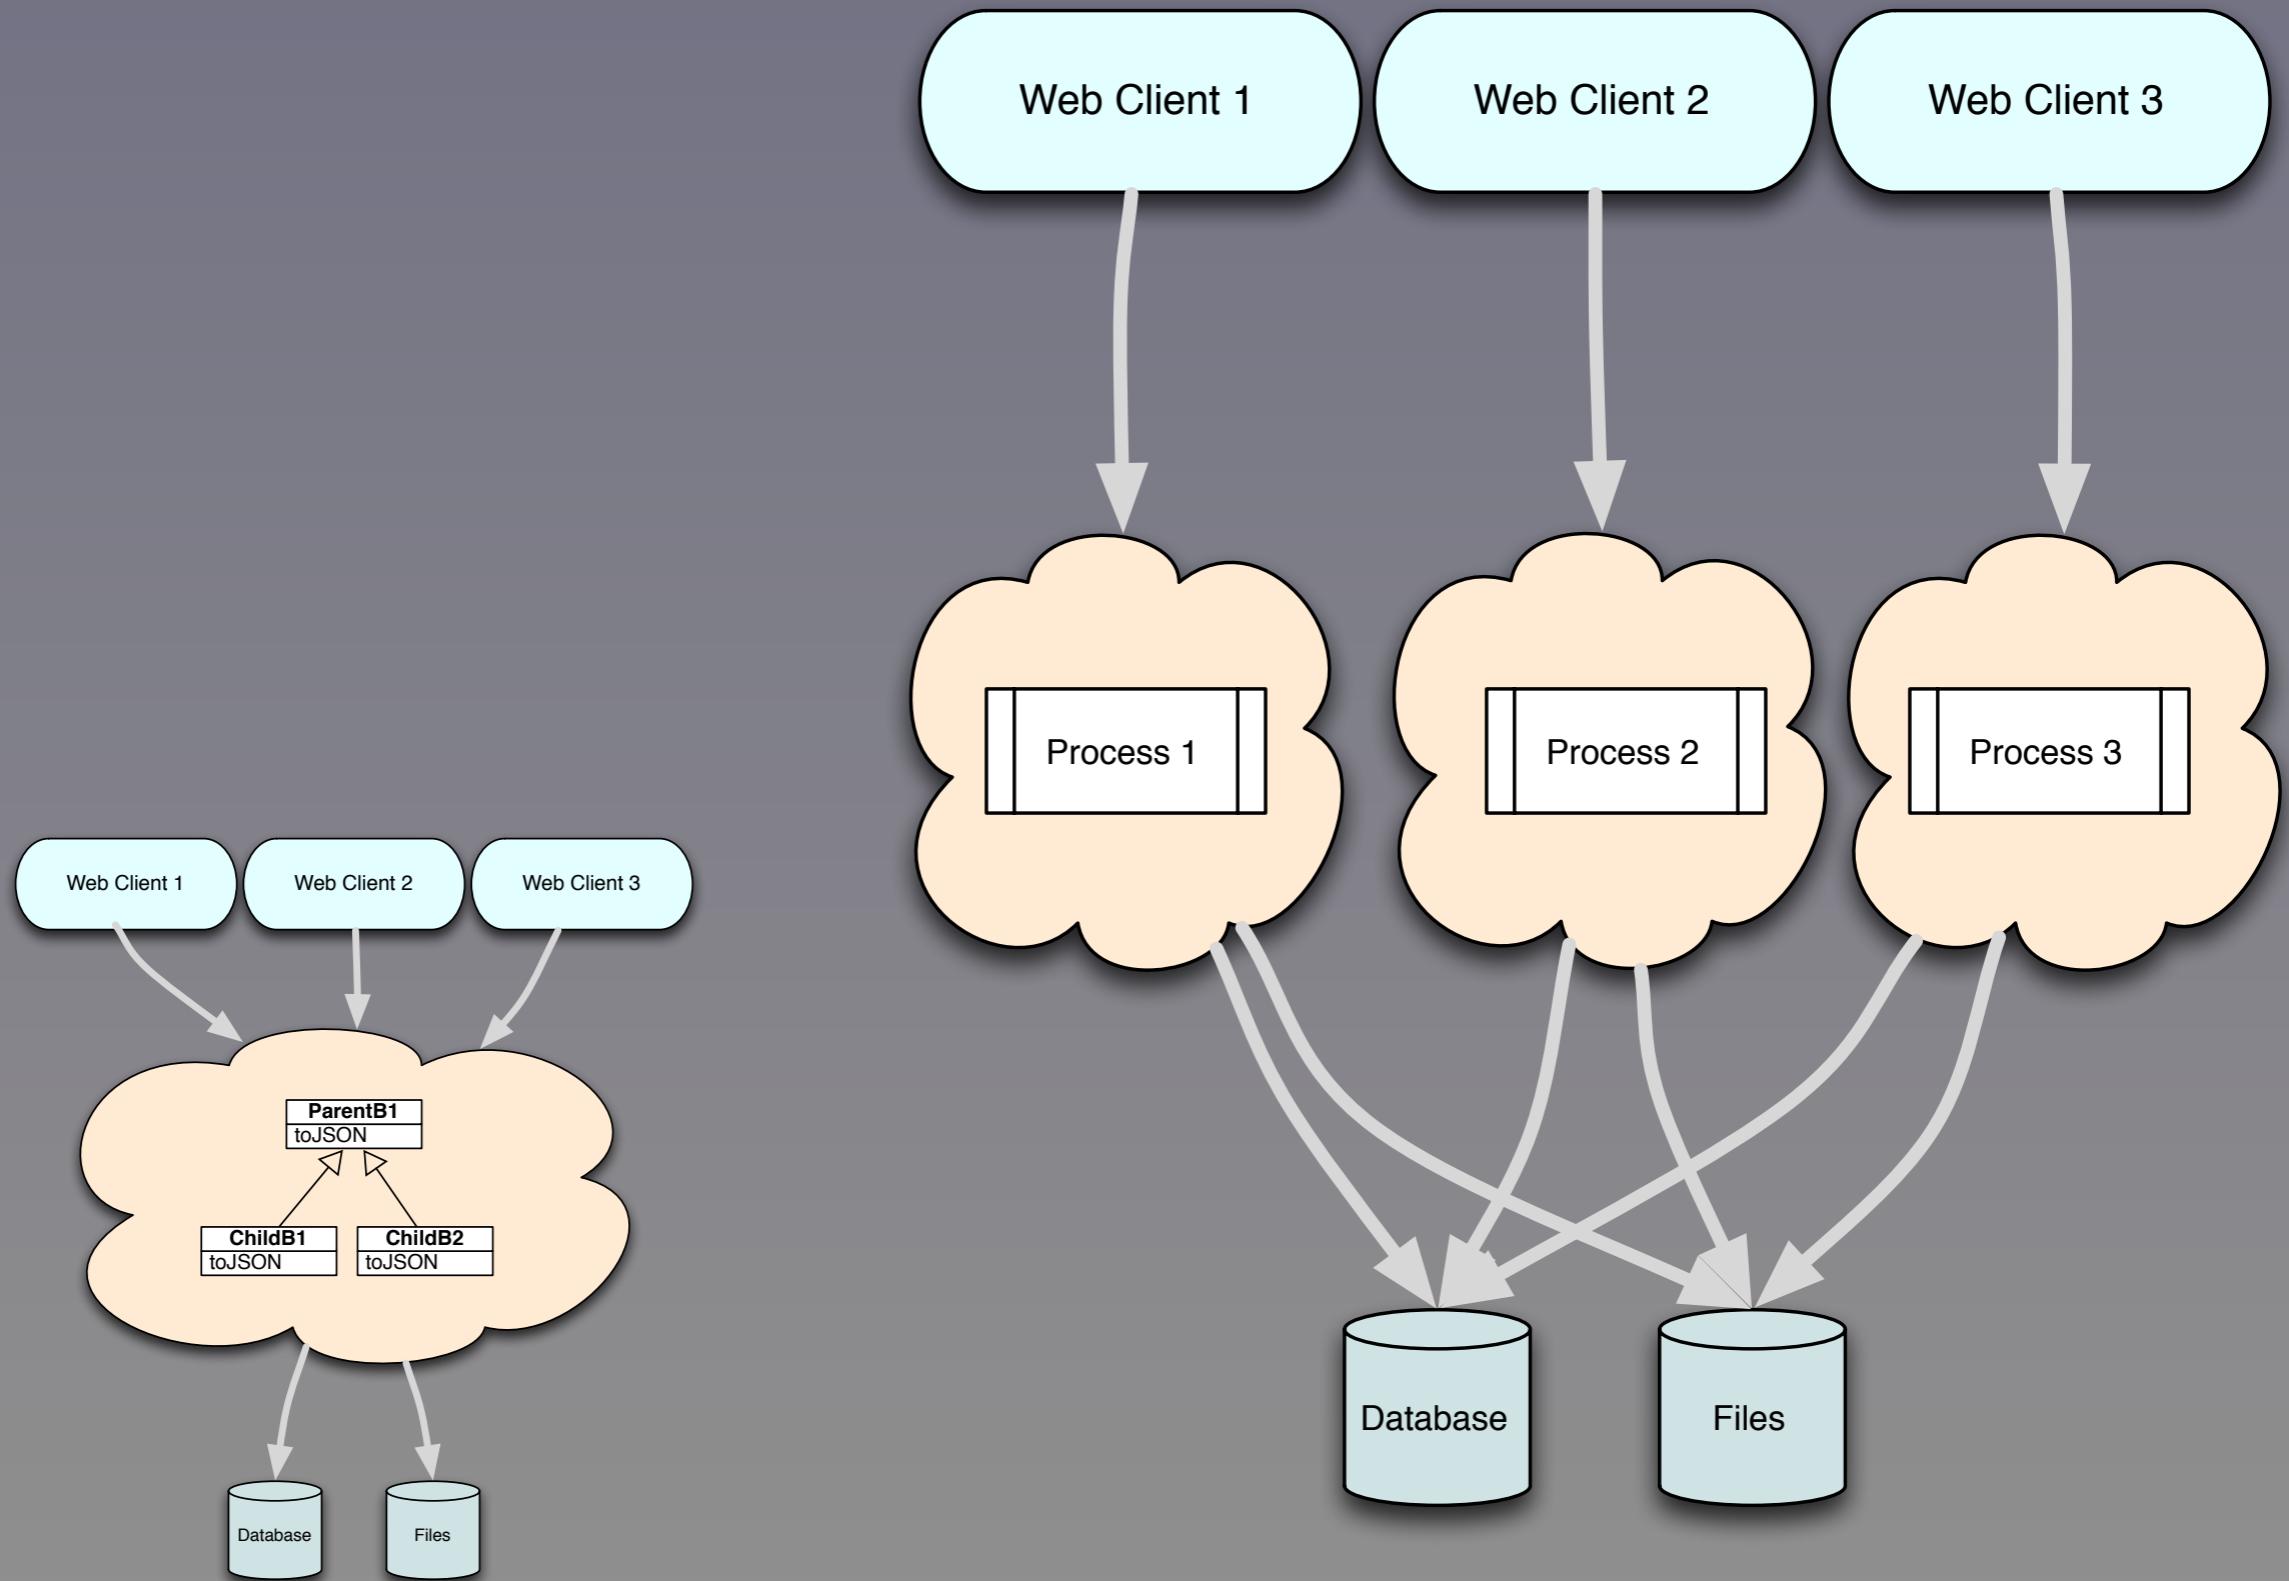

- Focus on:

- Lists
- Maps
- Sets
- Trees
- ...

But the traditional systems are a poor fit for this new world: 1) they add too much overhead in computation (the ORM layer, etc.) and memory (to store the objects). Sunday, July 7, 13

In a broader view, object models tend to push us towards centralized, complex systems that don't decompose well and stifle reuse and optimal deployment scenarios. FP code makes it easier to write smaller, focused services that we compose and deploy as appropriate. Each "ProcessN" could be a parallel copy of another process, for horizontal, "shared-nothing" scalability, or some of these processes could be other services...

Smaller, focused services scale better, especially horizontally. They also don't encapsulate more business logic than is required, and this (informal) architecture is also suitable for scaling ML and related algorithms.

- Data Size ↑
- Formal Schema ↓
- Data-Driven Programs ↑

# Hadoop is the Enterprise Java Beans of our time.

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

I worked with EJBs a decade ago. The framework was completely invasive into your business logic. There were too many configuration options in XML files. The framework “paradigm” was a poor fit for most problems (like soft real time systems and most algorithms beyond Word Count). Internally, EJB implementations were inefficient and hard to optimize, because they relied on poorly considered object boundaries that muddled more natural boundaries. (I’ve argued in other presentations and my “FP for Java Devs” book that OOP is a poor modularity tool...) The fact is, Hadoop reminds me of EJBs in almost every way. It’s a 1st generation solution that mostly works okay and people do get work done with it, but just as the Spring Framework brought an essential rethinking to Enterprise Java, I think there is an essential rethink that needs to happen in Big Data, specifically around Hadoop. The functional programming community, is well positioned to create it...

# MapReduce is waning

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

We've seen a lot of issues with MapReduce. Already, alternatives are being developed, either general options, like Spark and Storm, or special-purpose built replacements, like Impala. Let's consider other options...

# Successful replacements will be based on Functional Programming

```
import com.twitter.scalding._

class WordCountJob(args: Args) extends Job(args) {
  TextLine( args("input") )
    .read
    .flatMap('line -> 'word) {
      line: String =>
        line.trim.toLowerCase
        .split("\\\\W+")
    }
    .groupBy('word) {
      group => group.size('count) }
  }
  .write(Tsv(args("output")))
}
```

Copyright © 2011-2013, Dean Wampler, All Rights Reserved

Sunday, July 7, 13

FP is such a natural fit for the problem that any attempts to build big data systems without it will be handicapped and probably fail.

Let's consider other MapReduce options...
